The use of steel in skyscrapers was followed by its use in constructing fireproof factories. H. J. Heinz started his fireproof three-story factory in 1889. Most of America's cities had been devastated by fires, and insurance costs had soared by the 1880s. Fire was one of the main reasons that many companies failed. Fires had destroyed many American cities such as Chicago, Boston, and Pittsburgh. H. J. Heinz Company built its factory to be completely fireproof with steel beams and concrete fill between floors, which brought significant insurance savings for the company. The infrastructure was of structural steel from Carnegie Steel. The popularity of skyscrapers created a revolution in steelmaking and construction. Bessemer steel's limits were being reached in the late 1890s at around 12 stories of height. Structural beams required the higher-quality open-hearth steel to move beyond 12 stories. Carnegie purchased a brand-new Bessemer steel mill at Homestead and gutted it to make open-hearth steel for the structural steel market that would move buildings skyward.

Skyscrapers were as much a cultural as a technological advance. In the late 1890s, skyscrapers started to be viewed as real estate and rentable office space. Culturally, the New York World Building in 1899 is considered the first modern skyscraper. The New York World Building was built as commercial real estate versus a corporate headquarters. The New York World Building was financed by banker August Belmont as a real estate investment. The building had 950 separate offices to rent, and 4,000 people worked there. The New York World Building was 30 stories and 391 feet high. Chicago and New York became true business centers with these huge office buildings. The World Building also featured the electric elevator of Werner von Siemens, which was also a necessary technology for 30-plus-story buildings.

The next critical step in taller skyscrapers (moving beyond 30 stories) was the production of the Bethlehem Steel I beam. The I beam was lighter, but its design gave it more strength than the structural beams used at the time. The I beam was the invention of engineer Henry Grey, but it took the financing and building of a special rolling mill to make it a reality. Charles Schwab of Bethlehem Steel in 1907 made the investments necessary to change American skylines. Schwab

used his business connections to overcome the resistance of engineers and architects to using the new technology. The I beam was lighter and stronger, but it cost triple what the older H beam did. I beams gained popularity with their use in buildings for Gimbel Brothers, the Field Museum, and the Chicago Opera House. The beam quickly gained export markets. In 1909, the United States produced less than a million tons of I beams, but in 1929, it produced over 4 million tons of them.

There were many doubters, but the beam's use in New York's Metropolitan Life Building of 50 stories (700 feet) proved it to be a success. The Bethlehem I beam went on to change the skylines of Chicago and New York, with the Chrysler Building in New York reaching 77 stories (927 feet) in 1930 and the Empire State Building reaching 102 stories (1,250 feet) in 1931. Skyscrapers are great symbols of economic might. Today, we have the 2,717-foot, 160-story Burj Khalifa in Dubai.

Soda Fountain

A soda fountain is a mechanical device that dispenses carbonated beverages, or sodas. In the 19th and early 20th centuries, a soda fountain was a small lunch counter, usually inside a larger store—often a drug store.

The soda fountain was invented in the United States because people drank carbonated water in the belief that it had medicinal qualities. This viewpoint had come from as early as 400 BC. Hippocrates, an ancient Greek philosopher often regarded as the father of modern medicine, insisted that carbonated water cured diseases. From the 1300s to the 1600s, aspiring and amateur scientists experimented with creating artificial mineral or carbonated water. It was not until the 1770s that Joseph Priestley, an English preacher, found a way to create it by forcing fermentation gas from a brewery into plain water.

In the early 1800s, Benjamin Silliman, a teacher in Connecticut, made a breakthrough in developing the soda fountain. Suffering from depression in 1797, he visited the well-known Saratoga and Ballston Spas in New York State. He then took a job teaching chemistry and met Joseph Priestley. Silliman then traveled to London, where he witnessed the flourishing bottled mineral water industry, which influenced his desire to work in the field when he returned to the States in 1806.

Silliman used a “Nooth’s apparatus” to manufacture the carbonated water and found an apothecary in New Haven, Connecticut, to sell it. While demand was high for his water, he had no reliable bottles to put it in because Americans had not yet perfected glass bottles that could withstand the pressure of the carbonization. Instead, Silliman decided to use imported mineral water bottles from England. By selling mineral water in this fashion, he created the idea that the beverage could be enjoyed along with other people from all segments of society. They could gather and socialize while sipping their beverages at soda fountains.

During Silliman’s time, apothecaries used large contraptions to distribute carbonated water to their customers. Columns, urns, and faucets shaped like goose necks were the norm in dispensing the beverage. One of Silliman’s competitors, Joseph Hawkins, was another pioneer in selling mineral carbonated water to the masses. He also sold the beverage by the glass, and he manufactured carbonated water with a machine he invented in 1807.

As the years passed, soda fountains became elaborately decorated, using carved wood, polished marble, and beveled mirrors. Commonly, spigots were

shaped like goose necks and adorned with eyes, beaks, and bills. Urn-type fountains could include more than one spigot and could hold ice to keep the carbonated water cold. Urn spigots were decorated to look like fish, elephant’s trunks, or another animal. Urn-based fountains were made from bronze or silver-plated metal. Moldings and figurines were added for decoration.

“Soda jerks,” the men (generally) who worked at soda fountains, developed a number of novelty drinks by combining flavored syrup with carbonated water. Coca-Cola, for example, was originally sold as a syrup. Eventually, soda fountains added ice cream-based treats to their menus and sometimes light lunch fare like sandwiches and soup.

The soda fountain’s popularity and advancement continued into the mid-20th century. Post–World War II culture and the drive-through restaurant gradually caused the soda fountain’s popularity to decline, though a few of them still exist.

Spork

A spork is a hybrid eating utensil that combines the properties of a spoon and a fork into one piece of flatware. Sporks have a bowl shape similar to a regular spoon as well as several tines for spearing food.

The spork is not a new invention. In February 1874, Rhode Island doctor Samuel W. Francis received a patent for his “improvement in combined knives, forks, and spoons.” His awkward-looking utensil looked like a spoon with four tines on the business end and a short, flat blade that was grafted to one side of the bowl. Other fork-and-spoon combinations have

been in vogue at various times, although most have consisted of a flat handle with a spoon at one end and a two-tined fork at the other end. These utensils were used as serving tools rather than for eating.

The word “spork” dates back to at least 1909, when it first appeared in a dictionary. Since then, several patents and trademarks have been issued for a variety of spork designs. Modern sporks come in a variety of designs and are manufactured from plastic, stainless steel, aluminum, and titanium.

Steel Arched Bridge

In the city of St. Louis, right above the longest river of the United States, a bridge designed by James B. Eads has stood as one of most iconic structures since its 1874 opening. As an historic piece of architecture with elegant structure and unconventional design at the time, it has claimed numerous records as a bridge. At the time of completion, the Eads bridge was considered the longest steel arched bridge in the world, was the first bridge over a river in St. Louis, and was the southernmost bridge of the Mississippi river.

Eads made innovative use of steel and iron as main structural components to create a bridge that defied then-conventional wisdom. However, the path from design to construction of this immediate post-Civil War architecture was not as straightforward as it appears. The creator was as amazing as the creation itself. Eads was known as genius who taught himself to create the bridge without any prior experience. The entire project involved a series of struggles as well as political, legal, and medical issues. But the some of the other famous bridges around the United States

today all originated from his design. Eads acted as a bridge to innovation for the modern builders of today’s steel bridges.

The creator of the eponymous Eads bridge, James Buchanan Eads, was born in Lawrenceburg, Indiana, in 1820. He had limited access in academics due his parents’ financial problems. In 1883, as a penniless 13 year old, Eads arrived in St. Louis, Missouri. He first sold apples on the street, but then he moved up to a position as a clerk with a merchant named Barrett Williams. Williams possessed a private library and allowed Eads to read from his collections. This sparked an interest in Eads specifically in the problems of steamboats and their frailties. During this era, boats were liable to many mechanical dangers and often sank with expensive freights aboard. Business owners usually paid fortunes to recover these sunken cargos. Noticing a business opportunity, Eads created a submersible boat and a salvage business. He made a fortune from this first business and was able to retire by the age of 37 in 1857.

When the American Civil War started, Eads volunteered to assist the Union Army in creating an innovative battleship. In 1861, Eads entered a contract to build seven of these ships, which were called “ironclads.” They were covered by iron plates and carried large cannons. His ironclads debuted earlier than the famous ironclad CSS *Virginia* by John Ericsson.

With the conclusion of the Civil War, Eads came across the opportunity to create a steel bridge. Long-standing plans to create a bridge across the Mississippi in St. Louis had been revived because the river prevented the transportation of cargo in bulk by train. Without the bridge, freight had to be dropped off the train and loaded onto a ferry to cross the river, only to require a reverse of the process on the other side. This significantly raised the cost of transportation and discouraged businesses from shipping goods through St. Louis. Not only that, but some Chicago businessmen purchased the rights to a St. Louis bridge so that no one else could do it.

Despite this sabotage by the Chicago businessmen, the city of St. Louis proceeded to create the new bridge. But Eads faced another complication: his plan was considered too radical. It did go forward, but the

project caused 15 deaths and two permanent disabilities, and 77 others were severely injured. As the bridge neared completion on July 2, 1874, the builders ensured that the bridge could withstand 5,000 pounds per linear foot. On July 4, 1874, Eads's steel arched bridge officially opened, making it the world's first and biggest steel-arch bridge.

Between 1875 and 1879, Eads partook in building the first permanent mouth of the Mississippi River into the Gulf of Mexico by guiding sediment deposits. In 1884, Queen Victoria of England presented Eads with the Albert Medal of the Royal Society of Arts. This medal is awarded to an individual who proves distinguished merit in promoting arts, manufacture, and commerce. He was the first non-British person to receive the award. During the final years of his life, he worked on a project to cross the Isthmus of Panama. However, he opposed the Panama Canal project planned by Ferdinand de Lesseps and proposed the idea of a ship railroad instead.

On March 8, 1887, Eads suddenly passed away while recuperating in Nassau, Bahamas, bringing an end to his 66 years of life. Eads was a true inventor and an engineer who made a significant impact on the daily lives of citizens in his time and to this day. In fact, when the deans of U.S. engineering colleges were asked to vote on history's five greatest engineers, they selected Leonardo da Vinci, James Watt, Ferdinand de Lesseps, Thomas Edison, and James Buchanan Eads.

Stethoscope, Binaural

The stethoscope, commonly seen worn around the necks of medical personnel, is an important tool used to listen to sounds created by internal organs of the body. The modern binaural, or two-ear, stethoscope comprises a flat, disc-shaped resonator and two flexible tubes connected to a pair of ear pieces. The membrane of the resonator is placed on the patient's body to auscultate, or listen, to the sounds produced by the heart, lungs, blood vessels, and gastrointestinal tract. The word "stethoscope" is derived from the Greek "*stethos*" for "chest" and "*skopein*" for "examination."

Before the stethoscope was invented, early physicians used percussion or immediate auscultation to listen to a patient's chest. Similar to using a drum, percussion involved tapping on the chest and listening for sounds that indicated if the patient's lungs were congested with fluid. Auscultation provided more accurate results. Physicians placed their ears directly upon the patient's chest to hear heart and lung sounds more clearly.

Direct auscultation had several disadvantages. First, the skin-to-skin contact between physicians and patients increased the chances that a doctor might contract a louse infestation or other infection from the patient. At the very least, such close contact tended to be unpleasant if the patient had not bathed. Second were the technical concerns. The technique required careful placement of the ear and a quiet environment. Physicians often missed hearing important sounds that might indicate illness because the sounds weren't amplified and could be further muffled by excess tissue in muscular or obese patients. Finally, there were modesty issues associated with examining female patients.

The first stethoscopes widely in use were wooden tubes and were monoaural (they used one ear). In 1816, French physician Rene Laennec was uncomfortable performing direct auscultation on a plump, young female patient. He remembered seeing two children playing with a piece of wood and a pin; one child would scratch the wood with the pin, and the other would listen to the signal produced on the other end. Laennec rolled a sheet of paper into a tube similar to a hearing aid known as an ear trumpet and discovered that he

could hear the patient's heart sounds very clearly. Laennec used his stethoscope to investigate heart and lung sounds and compared his noninvasive diagnoses to observations made during postmortem examinations. The stethoscope allowed him to identify the different lung sounds produced by pneumonia, bronchiectasis, pleurisy, emphysema, and pneumothorax.

The first binaural stethoscope was proposed in 1829, when Nicholas Comins devised a hinged stethoscope that allowed the physician to assume more comfortable positions during examinations. Comins's sketches showed a binaural instrument, but it was not further developed. Around 1840, Dr. C. J. B. Williams constructed a binaural stethoscope using two bent pipes attached to a wooden chest piece.

In 1851, when flexible tubing made of tree sap became available, Irish physician Arthur Leared invented the modern binaural stethoscope. Soon after, in 1852, George Cammann refined the design for commercial production and distribution. The new stethoscope used rubber tubing to connect a headset and a chest piece. The head set had two ivory earpieces that were inserted into the physician's ears. The earpieces were connected by metal tubes made of silver and held together at a hinge joint. Two silk-covered tubes met at a hollow ball, which amplified the sound and was attached to the trumpet-shaped chest piece. Cammann did not file a patent for his stethoscope because he wanted it to be freely available for physicians' use. The Cammann stethoscope remained in common use for almost 100 years.

In 1961, Harvard professor and cardiologist David Lippmann invented the combination, or two-sided, stethoscope in use today. The chest piece bell had an open side for hearing low-pitched sounds. The other side was enclosed with a stiff diaphragm that filtered out low-pitched sounds. The firmer tubing transmitted sound more clearly, and the entire stethoscope was lightweight and convenient to carry. Lippmann sold his patent to the 3M Company, which continued to improve its acoustics and capabilities. Modern stethoscopes have tunable diaphragms, ambient noise reduction, and Bluetooth connectivity.

Stockyards

Stockyards are areas that contain multiple pens and sheds used to harbor livestock for the purpose of slaughtering for meat or selling. These places generally hold animals such as pigs and cows. After months of feeding, these animals are transported to a slaughterhouse, killed, and butchered. The stockyard is a complementary service to the packaging and slaughterhouse industries. In some places, the stockyard and slaughterhouse are nearby each other. Recently, stockyards have received a bad reputation for animal cruelty, poor sanitation, and generally poor health of the animals. Many people see them as unsustainable, environmentally unfriendly, and blights on communities.

There was a proliferation of American stockyards in the 19th century in response to westward expansion and railroads. Westward expansion and the decimation of Native American peoples allowed for increased cattle-grazing on private and public lands. Railroads provided a quick and affordable method of getting cattle from thinly populated Western territories and states to Eastern cities. Stockyards sprang up in these cities to hold and fatten Western beef before slaughter.

In 1844, a Cincinnati stockyard began selling meat outside the United States, creating an international market for American beef and pork. In 1844, it was reported that 26 Cincinnati firms provided over \$2.8 million in meat. Stockyards became an economic lifeline for some cities. The industry has grown a tremendous amount, especially since the American Civil War (1861–1865). Cities like Chicago became pork

capitals. Stockyards were often adjacent to railways and slaughterhouses and were able to sell outside their regions.

There was little public interest in the well-being of livestock in the 1800s and almost no state or federal regulations on it. In the 1870s and 1880s, there were improvements in mobile refrigeration that caused distribution systems to expand across states and dominate markets. Regulation of the market began during these times because these expanding industries violated the Sherman Antitrust Act.

During the Great Depression, meat consumption declined as Americans could not afford to buy it. With World War II, this changed, and stockyards and slaughterhouses found their business booming. After the war, livestock production increased exponentially. The U.S. Department of Agriculture (USDA) began to place letter grades on meat based on the animals' diets. Stores began to demand only meat that met USDA standards. Stockyard companies began to hire nutritionists and veterinarians to meet the standards for Prime and Choice beef. More regulation, such as that banning harmful feed and the introduction of the Wholesome Meat Act (1967) to regulate animal hygiene, was introduced.

The stockyard industry is a vital part of the American economy. Along with becoming a global industry that sustained cities, much innovation came with it. For example, the use of preservation was key for the packaging industry. Preservatives and salt were added to meat to increase usability. In addition, refrigerated trucks to transport meat were developed. Refrigeration was implemented in other transportation systems such as trains and boats.

Nonetheless, environmental experts and animal rights activists have made a strong case for ending the stockyard system. Vivid representations of abused and sick animals have turned some of the public against this type of meat production and toward sustainable, cruelty-free meat. One problem that needs to be addressed is the pollution that comes directly from stockyards. Stockyards also contribute to the methane gas problem, and methane remediation systems are expensive. Moreover, animal scientists point to the fact that stockyard animals eat grain, mostly corn—both because grain fattens animals quickly and because corn, as a federally supported monoculture, is cheap.

Cows are meant to eat grasses, not grain, and thus feedlot cows are unhealthy and unnatural, particularly given the massive amounts of antibiotics that must be fed to animals who live in such close proximity and in such unhygienic lots. Consumers now face a choice: consuming large amounts of readily available and cheap meat that is bad for the world they live in, bad for themselves, and bad for the animals; or consuming less meat from sustainable, cruelty-free, ethically raised, grass-fed animals.

Primary Document: Photograph of Chicago's Union Stock Yards (1907)

The Union Stock Yards in Chicago, Illinois, seen here in 1907, created a clearinghouse for cattle all over the West and Midwest. These yards dominated the Chicago meatpacking district for over a century, beginning in 1865. Stockyards like these changed ranching, signaling a shift to the modern agribusiness, the factory farm approach to agriculture.

Tape Measure

While there is no actual record of the first appearance of the tape measure, there is a record of who has improved it to what it is today. Tools of measurement were generally not portable before the creation of the tape measure. Historically, measuring implements were not flexible. However, measuring length with flexible material had been done before, such as with chains, rope, and strips of leather.

In 1864, William H. Bangs, a Connecticut inventor, filed a patent for a spring return pocket tape measure that functioned much like modern tape measures. It could be stopped at any point and had a button that caused the tape to spring back into the case.

In 1922, Hiram Farrand patented the convex tape measure, which became the standard shape for measuring tape. The convex shape allowed the tape to be spooled out in rigid form, making measuring much easier.

There is not much that can be improved about this product anymore. There are laser tools that judge distance and tape measures with digital screens that note the distance. The tape measure will not cease to exist, since it has applications that are unlikely to be replaced. Construction workers or those in the business of cutting wood use this technology constantly.

Taylor, Frederick (1856–1915)

Frederick Winslow Taylor, the “father” of scientific management, was an expert in efficiency. Critics of his day charged that “Taylorism” was an oppressive system that dehumanized workers. In spite of this, scientific management has been extremely influential.

Taylor was born in Germantown, Pennsylvania, on March 20, 1856. After a short apprenticeship in a small

machine shop, he took a full-time job at Midvale Steel Company in Philadelphia in 1883. At the same time, he enrolled at Stevens Institute of Technology in New Jersey, where he earned an engineering degree even though he never attended classes. His 12 years at Midvale were formative for him. He spent that time learning the different facets of the organization while he moved up the career ladder from gang boss, assistant foreman, foreman of the machine shop, master mechanic, chief draughtsman, to chief engineer. In fact, at Midvale, he developed the fundamentals of what later became known as “scientific management.”

At Midvale, Taylor became convinced that productivity was directly tied to the tools that were used to do a job and the techniques used to maintain those tools. His experiments led to the development of about 100 patented inventions that were in general use in factories by the early 1900s. His most notable innovation was the Taylor-White process for treating high-speed tools. Workers could cut through metal three times faster with treated tools. He received a gold medal for the Taylor-White process from the Paris Exposition of 1900.

Having improved the tools of the trade, Taylor turned his attention to the human aspect of labor. He was interested in finding a way to make humans more productive by reducing costs and increasing factory output. Based on his timed experiments at Midvale, Taylor developed and introduced ways to standardize work tasks. In 1898, Taylor took a job at a large steel company in Bethlehem, Pennsylvania, where he conducted his famous “time-and-motion” experiments and supervised the introduction of standardized work procedures. He concluded that productive workers engaged in timed, task-specific motions who were given the opportunity to earn 60 percent more wages would produce 380 percent more output.

After leaving Bethlehem, Taylor retired from factory work and devoted his time to consulting, lecturing, and writing. In 1905 and 1906, he served as president of the American Society of Mechanical Engineers. His most influential work was *The Principles of Scientific Management* (1911). Many business owners were attracted to scientific management in a desire to increase profits. On the other hand, many

labor leaders denounced scientific management, believing that it transformed human workers into nothing more than small cogs in a large industrial machine.

A high-profile strike brought on by resistance to the introduction of scientific management at a government arsenal led to a government investigation. Although the U.S. Congress did not mandate any changes pertaining to business practices, scientific management gained a bad reputation from the affair. Years later, motion pictures continued to promote a negative view of scientific management in the popular mind with iconic films like *Metropolis* (1927), the story of a futurist utopia only made possible by mistreating workers, and Charlie Chaplin's *Modern Times* (1936), which depicts human suffering caused by the efficiencies of modern industrialization.

Taylor, who genuinely believed that his principles were humane when applied correctly, was hurt by the negative view of his life's work, and he permanently withdrew from public life. He died of pneumonia in Philadelphia on March 21, 1915. In spite of criticism, the principles of scientific management were extremely influential.

Through the rest of the century, factory managers often promoted efficiency with the use of assembly-line-type work spaces where unskilled workers completed certain tasks within time limits. Educational leaders sought school efficiency by standardizing various aspects of the educational experience, including requiring standardized curricula and standardized testing. Many school administrators liked scientific management, because they believed that it promoted the most efficient use of available resources and encouraged accountability.

Tesla, Nikola (1856–1943)

Not many people recognized the man on the cover of *Time* magazine from July 20, 1931. He was an inventor and innovator who held over 250 patents worldwide and invented the method to power everything from small radios to our home appliances to huge factories: Nikola Tesla.

Tesla was born in Smiljan in the Austrian Empire (Croatia). His family was of Serbian descent. His father, Milutin Tesla (1819–1879), was an Eastern Orthodox priest. His mother, Djouka Mandic (1821–1892), was an inventor. She created tools and mechanical appliances to help with housework. She never learned to read or write, but she was clever.

Tesla was a student at the Real Gymnasium at age 14. He studied electricity and experimented with batteries, induction coils, water turbines, and motors. Tesla studied engineering at the Austrian Polytechnic in Graz, Austria, in 1875 with a Military Frontier Authority Scholarship. He was a good student until his third year, when he became bored and frustrated with his studies. He started gambling. He never graduated.

He needed money, so he started an apprenticeship to become a teacher. Then a more technical job became available, but it was in Hungary, so Tesla moved to Budapest in 1881. He worked for the Hungarian government's Central Telegraph Office Engineering Department as a designer and draftsman. He didn't make much money, but he continued to experiment on his own with electricity and magnetism.

When the new American Telephone Exchange Company opened in Budapest, he took a job there as a mechanic and mathematician. He would take apart equipment to see how it worked and looked for ways to improve it.

Tesla went to Paris in 1882. He worked for the Continental Edison Company. Incandescent lights were being installed throughout Paris. Thomas Edison's company used direct current (current in which electrons flow in a single direction), known as DC, to deliver power. Central stations were built throughout the city that supplied power for lighting homes and city streets.

Tesla submitted a plan to improve the company's dynamos (generators or machines that convert

Best remembered for the “current wars” with Thomas Edison, Nikola Tesla was an innovative and iconoclastic inventor, engineer, and physicist. While he was largely forgotten in the decades after his death, Tesla’s reputation has more recently been transformed, making him a recurring trope in contemporary science fiction. (Library of Congress)

mechanical energy to electrical energy). He received no compensation. When he saw ways to improve a process, he did so.

Tesla was transferred to Strasbourg, France, on the border with Germany in 1883. He worked on his idea for an alternating current (AC) motor. Alternating current does not flow in just one direction; it periodically reverses direction several times per second.

Tesla emigrated to the United States in 1884. He worked for a short time for Edison Machine Works in New York City. He presented his idea for an alternating current motor to his employers, but it was not well received. Tesla was given the opportunity to redesign Edison’s DC machines if he found a way to improve

them. Tesla maintained he was offered additional money for doing so. The company disagreed. Company officials said Tesla was never offered additional money. There was no written agreement so Tesla quit.

Tesla opened his own lab, Tesla Electric Light & Manufacturing Company. His first patent (number 335,786) in 1886 was for an improved arc lamp. The lamp provided uniform light with minimal flickering. Tesla split 50-50 with investors any money made from the patent for his AC dynamo (U.S. Patent 359,748, “Dynamo-electric Machine,” 1887). He needed money to continue his work.

Tesla demonstrated the advantages of using alternating current at an American Institute of Electrical Engineers meeting. Alternating current of high voltage could be sent over small wires for long distances. A transformer would reduce the high voltage to whatever voltage was needed at a location. It could then be distributed to businesses, factories, or homes, or for streetlights. Electricity could be transported from a single distribution point for hundreds of miles. AC-generating stations could be larger and so more efficient. Transmission wires could be smaller, providing more savings. Tesla’s findings were confirmed by others at the meeting.

Tesla met with George Westinghouse in 1888 in Pittsburgh, Pennsylvania. Westinghouse was an engineer who had invented the railway air brake. He also founded an electric company. He saw the potential of AC over Edison’s DC. Westinghouse and Tesla came to an agreement: Westinghouse would buy Tesla’s patent(s) and pay Tesla royalties based on watt per hour of electricity produced. Westinghouse also agreed to pay at least part of any legal fees from lawsuits. He offered stock in Westinghouse’s company.

Tesla moved to Pittsburgh to work on the AC motor. He stayed for a year and returned to New York City in 1889. Tesla became a naturalized U.S. citizen in 1891.

The Nikola Tesla Company was founded in 1895 to fund and promote Tesla’s patents and inventions. Tesla continued to work on a variety of ideas, from developing x-rays, a radio, wireless communications, robotics, bladeless turbines, and radio remote control of boats and torpedoes. Tesla worked on an induction coil (a transformer that transforms low-voltage AC

current into high-voltage pulses). The coil was patented January 9, 1894 (number 512,340).

Tesla received honorary degrees Columbia and Yale Universities in 1894. He died in 1943 in New York City.

Ticker Tape

Ticker tape was created by Edward A. Calahan in 1867 and patented by the U.S. Patent Office on March 31, 1868, to go along with the stock ticker. The stock ticker was invented as a cheaper and more reliable means of printing indicators that traveled across electrical telegraph lines for the stock market in gold, merchandise, and other stocks from distant businesses and trades. Other inventions attempted to fill the need but were expensive and more prone to breaking.

The paper of the ticker tape was divided into two sections that would be printed on by two separate wheels of the stock ticker machine. The first wheel had the alphabet, while the second wheel had numbers and a few letters. With the two wheels working simultaneously, information on specific businesses by abbreviated names would be printed on the first strip, and their stock prices were printed on the second strip.

Before the general acceptance of the stock ticker and ticker tape, financial information was shared through handwritten letters. Sending letters was slow and gave investors old financial information on their investments. While shareholders were able to see the

prices of their investments, they did not receive up-to-date information of how prices were increasing or decreasing. Still, letters were a more personal way of exchanging information and allowed relationships to be developed among shareholders and brokers. On Broad Street, brokers hired boys to listen to and write down the changing prices on the stock market and sold the information to potential shareholders. While the boys could get changing prices out fairly quickly, the prices on the ground floor were changing constantly, and it was nearly impossible to keep up by hand. The main problems with the use of handwritten notes on prices were the misinterpretation of information, losing or misplacing of said notes, and the potential for falsification.

The New York Stock Exchange made a contract for Calahan's stock ticker made him its sole supplier. By 1882, over 1,000 tickers were in New York City. With the introduction of the ticker to the stock market, the plan of the ground floor was changed. Brokers were able to stay connected to it with up-to-date changes in prices without the need to hire messenger boys, and there was a lower possibility of forgery.

Ticker tape was replaced in the stock market in the mid-1900s with the invention of computers and televisions. Though the electronic stock ticker was introduced in 1960 and is still in use today, it is not essential. It is kept more as a nostalgic representative of the stock market. However, ticker tape is still seen today in ticker tape parades in New York City. It takes the form of confetti that rains down on everyone below.

Tom Thumb Locomotive

The *Tom Thumb* locomotive was created by Peter Cooper in 1829 for the Baltimore and Ohio Railroad Company to show that steam engines were more efficient than the widely used horse-drawn railcars. The *Tom Thumb* was the first steam engine to be developed on American soil. The Baltimore and Ohio Railroad, created by Ellicott's Mills, had curves to go around rocks, which were considered impassable for locomotives. Therefore, horse-drawn cars were used instead. The ill-conceived line of the railroad was probably why the company went bankrupt. To fix this bankruptcy dilemma, Cooper wished to prove that steam locomotives were able to travel the railroad and curves better and faster than horse-drawn cars. He entered his in a race against a horse-drawn car belonging to Stockton and Stokes's stage cars. The *Tom Thumb* locomotive was in the lead, passing the curves at 15 miles per hour, until a belt slipped from the fan and could not be fixed fast enough before the horse gained ground and won the race. However, even with the loss, the Baltimore and Ohio Railroad Company offered a reward of \$500 to other designers who could create a locomotive able to pull 15 tons at 15 miles per hour.

The *Tom Thumb* model was smaller than other locomotives. It weighed less than one ton, with the cylinders being 3.5 inches in diameter. The spur wheel on the crankshaft had a pinion to aid in increased speeds. The wheels were 2.5 feet in diameter. The main fuel source consisted of anthracite coal. Peter Cooper did not have any diagrams or notes on developing the *Tom Thumb*, but Benjamin H. Latrobe provided sketches from his recollections of the model.

A functioning replica of the *Tom Thumb* locomotive is at the Baltimore and Ohio Railroad Museum to use in demonstrations and exhibitions. The replica was initially constructed for the Pageant of Locomotives at the Fair of the Iron Horse held in 1927. The replica differs from the original in that it weighs five tons instead of one, with various other changes.

The significance of the *Tom Thumb* as the first steam engine to attempt the impassable railroad of the Baltimore and Ohio Railroad Company opened the door for other inventors to step up. After Baltimore and Ohio accepted the *Tom Thumb* model, the horse-drawn cars were replaced by steam-powered cars in 1831.

Sagle, Lawrence W. 1948. "The Tom Thumb: Little Known Facts About First Locomotive Built in America Slowly Come to Light." *The Railway and Locomotive Historical Society Bulletin* 73: 46–53.

Primary Document: John Latrobe's Description of the *Tom Thumb* Locomotive (1830)

In 1830, John Latrobe, a lawyer for the Baltimore and Ohio Railroad, wrote about the excitement of seeing the first American-built steam locomotive, the Tom Thumb. Latrobe quite correctly predicted the potential impact of railways on travel and national expansion.

The First American Locomotive, Peter Cooper's "Tom Thumb" by John H.B. Latrobe

BY JOHN H. B. LATROBE

When steam made its appearance on the Liverpool and Manchester Railroad it attracted great attention here. But there was this difficulty about introducing an English engine on an American road. An English road was virtually a straight road. An American road had curves sometimes of as small radius as two hundred feet. For a brief season it was believed that this

feature of the early American roads would prevent the use of locomotive engines. The contrary was demonstrated by a gentleman still living in an active and ripe old age, honored and beloved, distinguished for his private worth and for his public benefactions; one of those to whom wealth seems to have been granted by Providence that men might know how wealth could be used to benefit one's fellow creatures.

The speaker refers to Mr. Peter Cooper of New York. Mr. Cooper was satisfied that steam might be adapted to the curved roads which he saw would be built in the United States; and he came to Baltimore, which then possessed the only one on which he could experiment, to vindicate his belief. He had another idea, which was, that the crank could be dispensed with in the change from a reciprocating to a rotary motion: and he built an engine to demonstrate both articles of his faith. The machine was not larger than the hand-cars used by workmen to transfer themselves from place to place; and as the speaker now recalls its appearance, the only wonder is that so apparently insignificant a contrivance should ever have been regarded as competent to the smallest results. But Mr. Cooper was wiser than many of the wisest around him. His engine could not have weighed, a ton; but he saw in it a principle which the forty-ton engines of to-day have but served to develop and demonstrate.

The boiler of Mr. Cooper's engine was not as large as the kitchen boiler attached to many a range in modern mansions. It was of about the same diameter, but not much more than half as high. It stood upright in the car, and was filled, above the furnace, which occupied the lower section, with vertical tubes. The cylinder was but three and a half inches in diameter, and speed was gotten up by gearing. No natural draft could have been sufficient to keep up steam in so small a boiler; and Mr. Cooper used therefore a blowing apparatus, driven by a drum attached to one of the car wheels, over which passed a cord that in its turn worked a pulley on the shaft of the blower. . . .

Mr. Cooper's success was such as to induce him to try a trip to Ellicott's Mills; and an open car, the first used upon the road, already mentioned, having been attached to his engine, and filled with the directors and some friends, the Speaker among the rest, the first journey by steam in America was commenced. The trip was most interesting. The curves were passed without difficulty at a speed of fifteen miles an hour;

the grades were ascended with comparative ease; the day was fine, the company in the highest spirits, and some excited gentlemen of the party pulled out memorandum books, and when at the highest speed, which was eighteen miles an hour, wrote their names and some connected sentences, to prove that even at that great velocity it was possible to do so. The return trip from the Mills—a distance of thirteen miles—was made in fifty-seven minutes. This was in the summer of 1830.

But the triumph of this Tom Thumb engine was not altogether without a drawback. The great stage proprietors of the day were Stockton & Stokes; and on this occasion a gallant gray of great beauty and power was driven by them from town, attached to another car on the second track—for the company had begun by making two tracks to the Mills—and met the engine at the Relay House on its way back. From this point it was determined to have a race home; and, the start being even, away went horse and engine, the snort of the one and the puff of the other keeping time and time. At first the gray had the best of it, for *his* steam would be applied to the greatest advantage on the instant, while the engine had to wait until the rotation of the wheels set the blower to work. The horse was perhaps a quarter of a mile ahead when the safety-valve of the engine lifted and the thin blue vapor issuing from it showed an excess of steam. The blower whistled, the steam blew off in vapory clouds, the pace increased, the passengers shouted, the engine gained on the horse, soon it lapped him—the silk was plied—the race was neck and neck, nose and nose—then the engine passed the horse, and a great hurrah hailed the victory.

But it was not repeated; for just at this time, when the gray's master was about giving up, the band which drove the pulley, which drove the blower, slipped from the drum, the safety-valve ceased to scream, and the engine for want of breath began to wheeze and pant. In vain Mr. Cooper, who was his own engineman and fireman, lacerated his hands in attempting to replace the band upon the wheel: in vain he tried to urge the fire with light wood; the horse gained on the machine, and passed it; and altho the band was presently replaced, and steam again did its best, the horse was too far ahead to be overtaken, and came in the winner of the race. But the real victory was with Mr. Cooper, notwithstanding. He had held fast to the faith

that was in him, and had demonstrated its truth beyond the peradventure. All honor to his name. . . .

In the Musée d'Artillerie at Paris there are preserved old cannon, contemporary almost with Crecy and Poitiers. In some great museum of internal improvement, and some such will at some future day be gotten up, Mr. Peter Cooper's boiler should hold an equally prominent and far more honored place; for while the old weapons of destruction were ministers

of man's wrath, the contrivance we have described was one of the most potential instruments in making available, in America, that vast system which unites remote peoples and promotes that peace on earth and good will to men which angels have proclaimed.

Track-Type Tractor

Benjamin Holt was the founder and president of the Holt Manufacturing Company of Stockton in 1883. The track-type tractor, also known as the "Caterpillar," was first field-tested in 1904 and later sold in 1906 as a steam engine. The name "caterpillar" was coined by a reporter who witnessed the tractor at work during a demonstration in 1905. The innovative tracks of the tractor replaced the regular rear wheels of a steam-powered traction engine to more easily move through the deep and muddy terrain of Stockton, California. Once Holt converted the engine from steam to gasoline in 1908, subsequent sales in 1909 increased higher than in any previous year. With the increased success, Holt patented the traction-type tractor in 1913. By the 1920s, the caterpillar was introduced into construction with experiments using different "heads." Now, bulldozer heads are standard on some models of the caterpillar.

The wheels of previous tractor models would sink into the deep mud of Stockton during fieldwork. To counteract this setback, even bigger wheels were used. Some were as massive as 45 feet wide and 12 feet in diameter. These wheel sizes quickly became unrealistic to work with, and Holt developed the idea of a continuous track as a replacement. The tracks were constructed of 3-inch × 4-inch wooden slats bolted to an endless chain. The chain was 9 feet × 2 feet. The belt track was powered directly and more evenly distributed the weight of the tractor. While the tractor was initially invented to aid in farming, it later moved into the construction industry with advanced models still seen today.

During World War I, the caterpillars were used instead of livestock for towing the Allied forces' supplies. Earlier war vehicles, such as the armored car, needed flat terrain to travel. This was not always available during the war, and all-terrain armored vehicles were in high demand. With the efficiency of the tracks, the caterpillar inspired the invention of tanks, which changed warfare forever.

For the future, it can be expected that tractors will conduct fieldwork automatically, without the need for a human driver. With technology in agriculture heading to unmanned vehicles, efficiency will increase and continual work can be done without breaks except for refueling and repairs. This will allow for increased crop yields to feed continued human population growth.

Transcontinental Railroad

The first locomotive rail train to travel from the Eastern seaboard to the Western coastline of the United States was known as the Transcontinental Railroad. The inception of the Transcontinental Railroad was a monumental venture not thought possible to achieve in its day. Not until the advent of electric wiring throughout the United States would there be such an impact on Americans socially and economically. Spanning across 1,000 miles over the most difficult terrain in the country, when finished, it surpassed expectations regarding moving goods and services, making a relative few staggeringly wealthy. The ambitious effort was fraught with scandal from the first moments of inception to the final strike of the last golden spike in Promontory, Utah, in 1869.

Financed by the U.S. government under the Pacific Railroad Act and with full support of President Abraham Lincoln, Congress approved the Union Pacific Railroad, a corporation chartered by the federal government. Approved under wartime circumstances during the American Civil War, the act was as much a business enterprise as a booster to Union nationalism in a deeply divided country.

Up until this time, overland travel to the western end of America was fraught with peril, with no guarantee of safety. Options for transportation included stagecoaches and local, short-run railway lines in steam cars. Depending on the final destination, travel often included both rail and stagecoaches to complete; frequent transfers between trains compounded the trouble of an often arduous journey. Those on a migration path to the West chose wagon trains, which were used primarily in the western expansion across the country. Also referred to as “prairie schooners,” they were able enough to carry goods, supplies, and shelter, allowing a family to subsist on the trail with other wagons. Others chose ocean travel by way of South America, a six-month journey. Either route was a dangerous enterprise with no assurance of reaching the final destination.

Early efforts to harness the power of mass transportation into an efficient system of economy, safety, and expediency played out in Europe and later, America, all with varying degrees of success. Oliver Evans

(1755–1819) applied for a U.S. patent in 1787 for the right to construct vehicles powered by steam for use both on road and rail networks. In 1804, Richard Trevithick’s (1771–1833) efforts paid off with England’s first engine-powered land vehicle resembling a potbellied stove on wheels with smokestack, similar to Evans’s patent in America. Trevithick may have been inspired by Evans’s work. Improvements over time continued, leading to the first railroad line in the world built in 1825 by John Blenkinsop (1783–1831).

Railroads and railroading had been a presence in American towns decades before the construction of the Transcontinental Railroad. The Quincy Granite Road, one of the earliest U.S. railroads, opened in 1830. The Baltimore and Ohio Railroad, 14 miles in length, opened in 1830 and by 1831 had ceased its horse-drawn operation, converting to locomotives. By 1836, there were over a thousand miles of railroad in the United States. Just over a decade later over, 5,200 miles of railroad track had been laid. In the 1850s, New York was host to the longest stretch of railroad in the world at over 400 miles. By 1852, over 10,000 miles of steel track sped goods, passengers, and services, with thousands more at the ready along the eastern half of the United States.

Once railways transitioned from horse-drawn trains to locomotives, there was no turning back. The first railroad passenger train’s appearance was a series of stagecoach-looking cars for passengers pulled on wheels powered by a wood-burning engine car with a tall chimney and an open-air wagon placed in between for hauling freight or barrels. Both European and American railways were similar in construction: wooden timbers laid flat upon the earthen ground, flanked by strip iron fastened together by spikes. Later, granite ties minimized derailments caused by loose rails.

Efforts to gain support for a railroad spanning the American continent began during the tenure of Abraham Lincoln’s presidency. Land surveys commenced to determine the safest, most direct routes along which to lay track. Legislation from Congress stipulated that railroad lines be divided between two competing companies. The Central Pacific, begun in California by five businessmen from Sacramento, was headed by Collis Potter Huntington, forming a partnership that would take the Central Pacific railroad east.

Simultaneously, the Union Pacific, originating out of Council Bluffs, Iowa, was headed by director Sidney Dillon and utilized contractors and brothers Jack and Daniel Casement. Jack served during the American Civil War and could therefore apply both acquired leadership from battle and railroad experience in laying over 1,087 miles of track to the West. Both the Central and the Union Pacific had financial incentives and subsidies, such as loans and grants for land, to implement the 1862 congressional directives as quickly as possible. Whichever side could gain the most ground would (in theory) reap the greatest financial gain for its investors.

Both the Union Pacific and Central Pacific experienced delays, setbacks, and conflict almost from the beginning. Acquiring a labor force equal to the monumental task of not only laying track but also navigating environmental extremes of snow and heat, Indian uprisings, and disease proved daunting. Relying upon his military background, Jack Casement rallied former soldiers from both Union and Confederate sides as far away as Chicago and New York. All told, over 1,000 men—Irish, Southerners, and Yankees alike, along with transients and fugitives from the law—provided the muscle for the Union Pacific. The Central Pacific labor force was composed from an unlikely source: thousands of Chinese laborers turned away from the gold fields of California. Immigrating to the United States during the California Gold Rush in 1848, these people were no strangers to hard work and were sought after as a reliable and cheap source of labor.

During the five years it took to finish the Transcontinental Railroad, remote sections of America's countryside morphed as each strip of track was laid, advancing upward of eight miles a day. Mountains were dynamited to give right-of-way to the locomotives. Temporary towns sprang up overnight as thousands of laborers needed shelter, food, and water and, just as quickly, they disappeared, leaving in their wake a forever altered landscape.

Corruption plagued both sides of the massive undertaking as greed dominated the enormous enterprise, fueled by realization that more money was made with building contracts before completion than with the final finished product. Though a fairly common practice in American railroad construction, it wasn't

until the *Crédit Mobilier* scandal uncovered a system of bribes reaching all the way to Washington, D.C. that the *Crédit Mobilier of America* was set up to oversee the financial and construction aspects of the Union Pacific Railroad. What it did in reality was severely deplete the financial resources of the railroad while lining the coffers of its trustees and participants.

The advent of the railroad left an indelible print on the lives of Americans of European, Asian, and African descent as well as Native American tribes. In a broader sense, the future economic life of those working in the railroad industry expanded a labor relations system that included union representation and organization. These workers were skilled, operating very costly locomotives, and not easily replaced; this empowered them to call a strike when working conditions proved exceptionally difficult. This was the impetus for future labor relations in the emerging corporate economy evolving in Victorian America.

The vibrant life of the American plains and of its native people was forever erased as the U.S. federal government took the land from Native people and gave it to the railroads. The Cheyenne and Comanche resisted the encroachment by whites, resulting in a federal military presence with forts built to ensure completion of the railroad. For the Chinese population post-construction, the Transcontinental Railroad no longer needed their work, so the newly unemployed men now competed for other work. They were, however, often thwarted by racial bigotry as whites feared that the Chinese immigrants would undercut wages. But for those who migrated and settled across the plains by choice, the advance of the railroad signaled a lifeline, creating and connecting communities, bringing more people to once-isolated areas.

Twine Self-Binding Harvester

The twine self-binding harvester was created to improve and enhance the conventional harvester. The difference between this harvester and other self-binding harvesters was that it used twine instead of wire to bind grain. The purpose of this improvement was to carry grain as it was cut by the harvester and deliver it in a continuous flow. While delivering the grain, it would keep the straw in a straight condition as well as in the right direction in relation to the binding device, even if the machine was traveling on flat or uneven ground. It also delivered the grain differently depending on whether the grain was long straw or short straw. This improvement operated as an intermediate attachment between a harvester and grain binder.

There are many different types of self-binding harvesters, but as for the twine self-binding harvester, its creation is credited to Marquis L. Gorham in the 1870s. The patent was issued on March 16, 1875. Gorham's intention was to improve upon Cyrus H. McCormick's wire self-binding harvester of 1872. To do that, Gorham invented an attachment that would be added onto self-binding harvesters.

Others improved upon Gorham's invention and incorporated it into newer harvesters. Examples include Appleby & Co., Backer Co., and Harvester Pridemore as well as Cyrus H. McCormick. McCormick would create his own self-binding harvester in 1881—a low-down self-binding harvester—and a steel self-binding harvester in 1892.

Marquis L. Gorham's twine self-binding harvester attachment was influential on agriculture, moving it toward more efficient and effective technologies that

would automate or remove the need for human interaction. Tasks like bundling, collecting, and tying were phased out of the harvesting process, and eventually, human interaction was removed completely. Twine was much cheaper, more versatile, easier to cut, and easier to dispose of. Marquis L. Gorham's twine self-binding harvester was a stepping-stone in the innovation of agricultural technology and led to the development of more automated harvesters.

Typewriter and QWERTY

Three American men patented the typewriter in 1868. The typewriter would allow more individuals to produce papers, novels, research, and business documents quickly. The typewriter was not only revolutionary at its inception, but it paved the way for future inventions, including the QWERTY keyboard layout, which has become the standard for almost all alpha keyboards.

In the 1860s, Christopher Latham Sholes, Carlos Glidden, and Samuel W. Soule worked together to create the first typewriter. It was patented on June 23, 1868. The first typewriter was unlike other typewriters to come, largely because of the layout of its keys. Unlike later typewriters, it did not have a key dedicated to every letter of the alphabet. Instead, the layout of the keys was like that of a piano's keyboard. It was very limited in its capabilities and, in the end, was unable to type every letter in the alphabet. Sholes, Glidden, and Soule patented an improved model of the typewriter soon after. This machine was much more usable.

The newer model had a key dedicated to each individual letter of the alphabet as well as keys for numbers. The layout had two rows: the top row was for

odd numbers and the second half of the alphabet, while the bottom row was for even numbers and the first half of the alphabet. Even though this model was a clear improvement over its predecessor, it was still horribly inefficient, and its letters were only uppercase.

In the 1870s, the typewriter was refined and improved. There were some modifications to the overall design of the typewriter, but the most frequent changes were still focused on the format and layout of the keys. In 1878, Sholes patented his most influential version of the typewriter, adding the QWERTY system designed to improve typing ease. Sholes did this because of all the complaints he had received about how inefficient the key placement was. He redesigned the keyboard layout so that the most commonly used letters were finger close, while the least used letters were farther away. It took nearly a decade for Sholes to create the most influential keyboard layout—one we still use today.

Sholes's contributions to the typewriter were extremely influential on future technology. Computers use the QWERTY keyboard format, as do cell phones, tablets, and more. Even touch screen keyboards use the QWERTY system, in part because it is now universally recognized.

Velocipede

“Velocipede” is a term that describes a human-powered land vehicle with two or more wheels. It has managed to become synonymous for the bicycle. It was invented by Karl von Drais, a German inventor, who originally called it the *Laufmaschine* (running machine). It was also called the “dandy horse.” Karl von Drais first rode it on June 12, 1817. It took 40

A forerunner to the modern bicycle, velocipedes, also called “bone shakers” because of their uncomfortable ride, enjoyed wide popularity in the late 1800s. Like tricycles, their pedals were attached to the front axel. (Library of Congress)

years for the term “velocipede” to be used in more generic ways.

Some of the early velocipedes have designs with as little as one wheel and as many as five. The ones with two wheels had pedals near the front wheel, while those with more wheels had to use levers to steer the back.

It was not until the 1860s that the first pedal-equipped bicycle was developed by the Olivier brothers, Pierre Michaux, and Pierre Lallement. The Olivier brothers are considered the first people to recognize the commercial potential of the bicycle. Pierre Michaux was a blacksmith in the 19th century who added pedals to the front wheels of the velocipede. He began building bicycles with pedals in the early 1860s, and his company sold them on a much larger scale than any other. His son, Pierre Lallement, is credited

for making the first true bicycle; he added a rotary crank mechanism and pedals that attached to the front wheel. The Michaux Company was the first company to mass-produce the velocipede and did so from 1857 to 1871.

People called these machines “boneshakers” because the tires of the velocipede were mostly of iron and made it uncomfortable to ride on cobblestone roads. Velocipedes became more popular for indoor riding in “velodromes,” which are similar to roller-skating rinks.

It was not until the 1870s that all-metal velocipedes were developed. It was also realized that larger front wheels meant farther travel with each rotation of the pedals. Then, solid rubber tires brought much smoother rides. It was this type of velocipede that was first called a “bicycle.”

Vending Machine

Vending machines are automated machines that dispense anything from snacks, beverages, tobacco, alcohol, and birth control products (including condoms) to lottery tickets. Though, typically, vending machines accepted coins or paper money, many now accept credit cards. American scientist and inventor Thomas Adams developed the first American vending machines in 1888. His American Chicle Company also invented chewing gum. “Tutti Frutti” and “Spearmint” are among his most famous gum flavors. Adams’s invention of chewing gum laid the foundation for his innovation of the vending machine. The chewing gums “Black Jack” and “Tutti Frutti” were his first products to be sold in

vending machines. Thomas Adams was not the inventor of the vending machine; many had already been created in Europe in the early 1880s. However, Adams popularized vending technology in the United States.

Adams was trying to manufacture rubber tires by transforming chicle into synthetic rubber when he accidentally dropped a piece of rubber into his mouth and was fascinated by its consistency. He added flavor to the gum and named it Chiclets—a gum still marketed today. His American Chicle Company was the most successful gum company in the 19th century, and it became a monopoly in 1899 when it combined with the six largest gum manufacturers in the United States and Canada.

Adams’s positioning of the vending machines turned out to have a significant impact on the success of his business. He placed his first vending machines in busy New York City subway stations, where consumers could easily purchase chewing gum for a penny while they waited for their trains. Vending machines, which did not require a salesperson, were something new and popular in the United States back then. Another reason that the vending machine was successful was the rising popularity of chewing gum, since it was easy to chew in public and very inexpensive. The fact that gum did not deteriorate like other candy made it a perfect choice to be sold in vending machines. Other products, such as chocolate bars, were simply not suitable for hot weather conditions.

Compared to the vending machines we know today, Adams’s first vending machines were very simple and functioned purely mechanically. Today’s machines use electronics and multiple motors for dispensing a variety of products. His had a coin slot, a compartment where the product was supplied, and levers that activated its mechanism. Some even had animated figures for entertainment purposes. Many vending machines often did not work as expected, and their simple system made it easy to trick the machines. A well-developed coin-detection mechanism simply did not exist, which made it possible for customers to pay with any coin they had handy. Some customers even attached a string to a coin to pull it back out of the machine once the gum had been supplied. This, however, did not influence the success of the machines.

Over the years, more and more product variety was added to vending machines all over the world. In the 1930s, sodas like Coke and Pepsi were offered for the first time. Postcard-vending machines enjoyed a brief period of popularity, as did machines that dispensed small toys. In the late 20th and early 21st centuries, vending machines have been used to distribute items as varied as books and fishing bait. In the 1950s and 1960s, a person could buy life insurance from a vending machine, as well as molded plastic figurines. In the 2010s, marijuana became available through vending machines in states where the drug is legal.

Besides changes in product variety, vending machine technology also improved throughout the years and is in fact still improving. Support for accepting bills rather than coins made the customer experience more flexible. Between 2011 and 2013, retailers added the feature of using a credit card and even smartphones as payment options. Vending machines continue to be popular food-dispensing machines and can be found in places from school campuses to recreation parks.

Vibrator

The vibrator is a mechanized device used primarily for sexual pleasure, employed most often but not exclusively by women. Vibrators are designed in several varieties, including for clitoral, transvaginal, or rectal stimulation, or some combination thereof. Some models, such as the Hitachi Magic Wand (the number-one selling brand in the United States), are nominally intended for body spot-massaging. Since its development in the 1870s, the vibrator has evolved from a

physician's instrument to a consumer health panacea and finally to a recreational sex toy.

From antiquity into the early 20th century, physicians routinely masturbated their female patients. Doctors administered manual genital massages to women suffering from nervous disorders such as hysteria, nymphomania, or neurasthenia. Many of these conditions were ambiguously defined and today might be diagnosed as anything from anxiety to sexual frustration. This treatment reflected an androcentric model of sexuality that dismissed the female capacity for pleasure and reduced sex to two steps: penetration and male orgasm. Because this normative framework did not consistently satisfy the supposed aberrant functioning of women's sexual desire, relieving these "disorders" fell within the medical realm. Physicians sometimes instructed midwives or husbands in pelvic massage but usually performed the task themselves.

The 18th-century advent of steam and electrical power fundamentally changed the world. Steam engines and electricity allowed humans to travel and thrive in unprecedented numbers. They also introduced novel orgasm-inducing techniques and eventually inspired the first vibrator models. Some inventive physicians sent hysterical patients on locomotive trips over rough track to induce orgasm. Contemporary medical literature noted similar effects from horseback riding, operating foot-powered sewing machines, and, by the late 19th century, bicycle pedaling. Though many questioned such unorthodox practices, medical professionals understood the industrial-era logic of mechanizing labor.

By the second half of the 19th century, some doctors were experimenting with electric hydrotherapies, or douches containing an electrical current. Other devices included rubber-handled metal rods or rollers warmed by electrical current. Based on the observed efficacy of electric and vibratory stimulation, in the 1870s, English physician and inventor Joseph Mortimer Granville developed the first (enormous) battery-powered vibrator. Granville doubted its utility to treat nervous disorders, indicating that orgasm's utility was not an undisputed consensus, but nonetheless, the vibrator was used for the first time publicly on a hysterical woman at the Pitié-Salpêtrière hospital in Paris. No longer would doctors labor for up to an hour to

relieve patients; instead, they could conclude a session in as little as 5 to 10 minutes.

By the turn of the century, several models of vibrator had flooded the market. In response, physicians unsuccessfully experimented with the use of vibrators elsewhere on the body to treat a number of conditions, including on the head for baldness, on the joints for arthritis, and on the stomach for obesity. Even men's impotence was treated with vibration.

Medical professionals soon abandoned vibrator use beyond its verified capacity to ameliorate female nervous disorders. Still-productive manufacturers recognized the commercial potential of vibrators as consumer products and quickly began marketing them to laypeople. Advertisements promised that vibration could strengthen muscles as efficiently as exercise and miraculously cure internal maladies such as indigestion when applied to the body. Mindful of appearances, doctors purchased only the most sophisticated models.

Still, vibration had already departed the exclusive province of medicine and would never return. The electrification of most urban American homes by 1900 invited new electronic appliances such as the sewing machine, fan, teakettle, toaster, and vibrator. Convenience and price, roughly the cost of four to five doctor visits, pushed many women to buy their own vibrators. Mail-order versions had largely replaced medical contraptions by 1920. Vibrator advertisements and purchase abruptly discontinued during the next decade, probably due to the explosion of vibrator use in contemporary pornography, which shattered the respectable veneer crafted by advertisers in previous decades.

Vibrators were relatively rare commodities from 1930 into the 1960s, only occasionally appearing for sale as "massagers" in downmarket magazines. The sexual revolution of the 1960s, brought on by the birth control pill, youth counterculture, a growing feminist movement, and advances in sexology, recovered the vibrator from obscurity. Marketing for the newly cordless device actually highlighted its sexual function, though some like the Hitachi Magic Wand, the most popular vibrator in America after its introduction in 1968, simply advertise themselves as "personal massagers."

Vibrator manufacturers continue to innovate as technology improves. Newer models boast adjustable speeds and novel attachments, lifelike appearances (when shaped like a penis or other object), and remote-operated ones in sizes small enough to be discreetly inserted and capriciously activated. American culture has embraced the return of the vibrator. A 2009 study found that about 53 percent of women aged 18 to 60 have used vibrators, and recent users indicated more positive sexual function.

Water Heater

Norwegian American Edwin Ruud invented the first modern water heater in 1889. Ruud's invention was a gas-powered, storage tank-type heater.

Edwin Ruud was born in Askin, Norway, on June 9, 1854. He immigrated to Pittsburgh, Pennsylvania, in 1880. Ruud worked with George Westinghouse to develop products related to gas power. He left Westinghouse to focus on water heater technology and established Ruud Manufacturing in 1897.

Prior to Ruud's invention, water heating was uncommon in homes and for only the very rich. No one knows who created the first water heater; they did exist before Ruud. But they were expensive, unreliable, and difficult to operate. Ruud improved the design and created an affordable and safe heater that became popular in the United States. The first patent for this product was issued in 1889.

Previous water heaters would store water and heat it, meaning that there was a limited amount of hot water one could use before having to wait for the tank to refill. Diagrams of Ruud's water heater show that it utilized a coil system, which water would pass through above an open fire. These systems relied on natural gas for power. In addition, Ruud's diagrams suggested road maps for plumbing pipes that would carry hot water throughout a house.

Since the 20th century, tankless water heaters have been gaining popularity, because they are both environmentally friendly and less expensive to operate than traditional water heaters. Solar-powered water heating also exists, with the heaters working in conjunction with solar panels.

Westinghouse Air Brake

The railroad industry, more than any other, defined the 19th-century explosion of technology and invention. It was the industry that birthed Thomas Edison, Andrew Carnegie, Henry Bessemer, and George Westinghouse (1846–1914). The railroad industry maintained almost 100 years of exponential growth, driving a world industrial boom spurred partly by Westinghouse's railroad technology. In 1850, there were only 9,000 miles of track in America; by the end of the Civil War in 1865, there were around 35,000 miles. By 1874, there were 77,740 miles, and by 1900, there were 198,964 miles. At the time of Westinghouse's death in 1914, there were over 250,000 miles of track.

By 1890, the American railroad industry's gross income exceeded \$1 billion, with the capital invested totaling over \$10 billion. The weight of goods moved increased enormously—from 90 million tons in 1860 to 235 million in 1880 and 425 million in 1900. These are staggering numbers even by today's standards. The 19th century's richest men, such as Cornelius Vanderbilt, John D. Rockefeller, Carnegie, and J. P. Morgan, made their money in the railroads' growth. Innovation and involvement in the railroad industry was a way to riches from 1870 to 1920.

Yet, as the railroads grew, accidents grabbed the headlines with grim news of death and injury. In 1853, President Franklin Pierce's young son was killed in a passenger train derailment, and Charles Dickens was in a major brake-failure wreck in 1865. An 1856 crash in central Pennsylvania killed over 50 people, mostly children on their way to a Sunday picnic. The public was becoming fearful of rail travel, and newspaper editorials called for industry action on safety. If the industry didn't address the problem, the government would step in to regulate it. Besides passenger safety, the lack of an adequate braking system also affected business by limiting the length of trains to 10 freight cars.

The hand brake system in place required coordination and muscle power. The locomotive engineer would start throttling down the engine as he signaled the brakemen with the whistle (known as the "down brakes whistle"). A brakeman was assigned between every two cars on the train. The brakeman would begin the process of applying friction brakes on each car by turning a hand wheel known as the horizontal wheel, located on a vertical post at the end of each car; the hand wheel multiplied the force of the brakeman's muscles. The needed strength of the brakemen was the source of the term "Armstrong system." The hand wheel pushed brake shoes on each car against the wheels. After the brakes were applied to one car, the brakeman jumped to the other car to apply its brakes. Poor coordination between the brakemen could cause "locking" and serious danger to both the passengers and the brakemen. The brakemen had to race from car to car, often on roofs slippery with ice, snow, and rain. It was estimated that 1,000 brakemen were killed each year and another 5,000 injured.

George Westinghouse already had a railroad equipment business and was looking for new products. He had been a vigorous reader of the technical and engineering journals from his earliest days at his father's plant. By 1868, compressed-air tooling was making news as new tunnels were being built all over the world. Westinghouse immediately saw the application of compressed air to railroad braking as a means to transfer energy to a braking system. A Pittsburgh train was equipped with the Westinghouse system in September 1868. (This date has been confused with April 13, 1896, the actual date that the patent was issued.) The train left a tunnel at 30 miles per hour only to see a merchant and his cart stalled on the street crossing. The train hit the brakes, stopping in time—a spectacular demonstration for Westinghouse's innovation.

If done well at 30 miles per hour, hand braking could stop a train within 1,600 feet. The Westinghouse "straight air brake" could do it within 500 feet. Word of the trial traveled quickly in local railroad circles, but the railroads were cautious. First, to many railroad executives, brakes were a safety issue, not a profit issue. In fact, Westinghouse's success struck fear in many because of the potential cost of converting all existing trains. One estimate was that \$40 million would have been needed in 1875 to convert the industry (equivalent to as much as \$1 billion in today's money). In July 1869, Westinghouse Air Brake was formed with a board of directors from the enthusiastic railroad executives. The board consisted of 22-year-old Westinghouse, Robert Pitcairn, W. Card, Andrew Cassatt, Edward Williams, G. Whitcomb, and Ralph Baggaley. The capitalization was \$500,000. Westinghouse sold the railroads on the air brake, showing that it would not only be a savings compared to the federal regulation that was moving through Congress, but that its use could more than triple the tonnage carried on freight trains. By 1874, Westinghouse brakes were on 20 percent of the nation's trains.

Westinghouse needed to standardize his parts and assembly to make his endeavor a commercial success. His manufacturing system was as revolutionary as his air brake. With the booming sales of the automatic brake, Westinghouse was in need of good mechanics and machinists. Hourly wages for such skilled employees were around \$2.50 per hour, but Westinghouse

devised a piece rate system in which employees could earn as much as \$4 an hour. Westinghouse's preceded the famous Frederick Taylor piece-incentive system by 20 years. Westinghouse's manufacturing system was the first to offer employee pensions and health care, and he developed a system of internal education and paid employees to go on to attend college. He was one of the earliest manufacturers to hire women in the factory.

Westinghouse featured his braking system at the 1876 Philadelphia World's Fair. By 1879, Westinghouse had installed his system on 3,600 locomotives and 13,000 cars. In 1893, Congress required the air brake and automatic coupler on all trains and passed the Railroad Safety Appliance Act. The act was the result of the work Westinghouse and his friend William McKinley, chairman of the Ways and Means Committee (and future president). When Westinghouse started making air brakes in 1869, freight trains were 15 cars long, carried 300 tons, and averaged 30 miles per hour. At his death in 1914, they were 130 cars long, carried 7,000 tons, and averaged 60 miles per hour. The brake gave huge profits to the railroads. Westinghouse brakes were on over 3 million cars and 80,000 locomotives in this country alone by 1916, and Westinghouse had covered as much as 70 percent of the world market.

World's Fairs

World's fairs, or expos, are public exhibits that showcase manufacturing, arts and crafts, science, technology, and other aspects of a collection of countries.

Modern world's fairs can trace their heritage back to the 1844 French Industrial Exposition and the 1851 Crystal Palace Exhibition in London, formally known as the Great Exhibition of the Works of Industry of All Nations.

Early fairs were held wherever and whenever a country decided to create an exhibit, but in November 1928, 31 nations came together to form the Bureau International des Expositions (Bureau of International Expositions, or BIE). The organization's role was a supervisory one, and by officially sanctioning world's fairs, it was thought that the BIE would help countries maintain fiscal control on their exhibits by limiting the number of events in progress at any given time. World's fairs that have been registered with the BIE may be held once every five years, and registered expos (smaller events) may be held between world's fairs.

Throughout the 19th century, world's fairs mainly showcased advancements in industry and inventions, but by the mid-20th century, they were pursuing cultural exchange and understanding in addition to technology and science.

The earliest unofficial world's fair held in the United States was the 1853 New York City Exhibition of the Industry of All Nations, which opened on July 14, 1853. The fair was dominated by the New York Crystal Palace, an opulent steel and glass structure modeled on the British Crystal Palace of 1851. Reservoir Square, on the outskirts of the city, was chosen for the location, and an architectural competition was held, which was won by George Carstensen (1812–1857) and Charles Gildemeister (1820–1869).

Adjacent to the Crystal Palace was the Latting Observatory, a 315-foot wooden tower that allowed visitors a panoramic view of New York and New Jersey. At the fair, Elisha Otis demonstrated his new elevator, which was equipped with a safety brake.

The 1876 Philadelphia Centennial Exposition was the first official world's fair to be held in the United States. It was officially opened on May 10, 1876, by President Ulysses S. Grant (1822–1885) and ran until November 10. Thirty-five countries participated in the fair, which drew an estimated 10 million visitors to its more than 30,000 exhibits, including a 650-ton, 70-foot-tall Corliss steam engine and a telephone.

American animals were put on display, along with rocks and minerals. Fifty-three Native American tribes camped on the fairgrounds, having been brought to the fair to show their way of life to attendees.

The 1893 Chicago World's Columbian Exposition was homage to the 400th anniversary of Christopher Columbus's expedition to the New World. The fairgrounds were designed by landscape architect Frederick Law Olmsted (1822–1903), who settled on a classical theme for the exposition's buildings. Dubbed "the White City," the fair's architecture helped spur the adoption of the City Beautiful Movement philosophy of urban planning.

The fair covered more than 600 acres of land and opened to visitors on May 1, 1893, running through the end of October. More than 27 million visitors flocked to the fair, taking rides on the Ferris wheel designed and built by engineer George Washington Gale Ferris Jr. (1859–1896). The wheel was 264 feet tall and could carry more than 2,000 passengers at a time.

Many technical innovations were displayed at the fair, including the first fluorescent lightbulbs, and at night, the buildings were lit by electric lights powered by alternating current. The Yerkes telescope was on display in the Manufactures and Liberal Arts Building until the building caught fire in November.

The Columbian Exposition was the first world's fair to include national pavilions, and nearly 50 countries attended, as well as many states and territories. The Liberty Bell was sent from Philadelphia and was put on display in the Pennsylvania Building.

The next American world's fair was the 1901 Pan-American Exposition held in Buffalo, New York. It was known as the "Rainbow City" for the liberal use of color in its architecture, such as the 375-foot green Electric Tower lit at night by more than 40,000 lightbulbs with power drawn from Niagara Falls.

The Pan-American hosted a variety of exhibits that included the Model Dairy, agricultural machinery, and an infant incubator that demonstrated its use in the treatment of premature babies.

In 1904, St. Louis, Missouri, hosted the Louisiana Purchase Exposition in celebration of the Louisiana Purchase centennial. More than 200 buildings housed a variety of technological, scientific, and anthropological

exhibits, which included indigenous peoples “on display” and a reconstruction of a traditional Igorot Philippine village. The scientific exhibits included a demonstration of wireless telegraphy and meteorological balloons.

The 1915 Panama-Pacific International Exposition was held in San Francisco’s Marina District to celebrate the completion of the Panama Canal. The fair was officially opened by President Woodrow Wilson (1856–1924) on February 20 and ran through early December.

Twenty-four countries participated in the 635-acre fair, and its buildings included the Tower of Jewels, which contained thousands of fragments of colored glass, and the Palace of Fine Arts, which is the only remaining structure from the fair. The Hawaiian presence popularized the ukulele.

The 1933 Chicago World’s Fair opened on May 23, commemorating the city’s 100 years of incorporation with the theme “A Century of Progress.” Buildings included the Havoline thermometer, a 218-foot structure that used neon lights to display an accurate temperature. The Travel and Transportation building housed a railroad exhibit, and the Homes of Tomorrow Exhibition introduced consumers to new building materials and prefabricated homes.

The 1939 New York World’s Fair opened on April 30, 1939, with the theme “Building the World of Tomorrow.” It covered 1,216 acres of a former dump in Queens and boasted some of the most memorable architecture of any fair, including the two buildings that became its symbols: the Trylon and Perisphere.

The fair was organized into seven zones, which included the Government Zone and its Hall of Nations and country pavilions, the Communications and Business Zone, the Transportation Zone, Amusement Zone, and Food Zone. The Futurama ride, sponsored by General Motors, gave attendees a taste of what life in the future would look like.

Among the technology exhibited at the fair were air-conditioning and television sets. President Franklin D. Roosevelt became the first American president to appear on television when RCA transmitted his opening speech.

The 1939 Golden Gate International Exposition was held on San Francisco’s man-made Treasure

Island, with the theme “Pageant of the Pacific.” The fair’s name acknowledged the newly built Golden Gate and San Francisco–Oakland bridges and was intended to honor their construction, as well as promoting unity in the Pacific.

The fair’s architectural style combined elements of eastern and western design, which later became known as “Pacifica,” named for the statue of the goddess of the Pacific. The fair was bisected by two main thoroughfares that met at the Court of Honor, dominated by the 400-foot Tower of the Sun.

The 1962 Seattle Century 21 Exposition opened on April 21, 1962, on 74 acres of land. The fair’s iconic 605-foot Space Needle lifted thousands of attendees to its 520-foot tall observation deck, while the monorail carried them around the fairgrounds, which included buildings that housed exhibits on science, commerce, art, and entertainment.

Back on the east coast, the 1964 New York World’s Fair opened in April 1964 on the original site of the 1939 fair and ran through October 1965, drawing an estimated 52 million visitors. It included industrial, international, federal and state, and transportation exhibits, with a heavy focus on a utopian future where machines and modern materials would make life easier.

The fair’s modern architecture included the 120-foot stainless steel Unisphere and the New York State Pavilion, both of which remain. Attractions featured Disney’s “Small World” exhibit, Dinoland, and the Futurama II ride, while technology on display included a demonstration of color television and computer-related technologies.

The 1968 San Antonio HemisFair featured a variety of national and corporate pavilions; there was the 1974 Spokane, Washington, Expo ’74, which eschewed technology in favor of environmentally themed exhibits; and the 1982 Knoxville International Energy Exposition.

The 1984 New Orleans Louisiana World Exposition was the last world’s fair to be hosted in the United States, which has not been a BIE member since 2001.

Wright, Wilbur (1867–1912) and Orville (1871–1948)

Orville and Wilbur Wright, known by their joint moniker as “the Wright brothers,” were American inventors, engineers, and aviators known for designing, constructing, and piloting the first powered, controlled airplane. Prior to their first flight from Kitty Hawk, North Carolina, human flight had been achieved through aerostats, lighter-than-air vehicles that achieved lift via gas envelopes, such as hot air or hydrogen gas balloons. The closest semblance to powered flight at the time was the *LZ-1* created by Count Ferdinand von Zeppelin (1838–1917), the first rigid airship. The Wright brothers demonstrated that an aerodyne, an engine-driven, heavier-than-air craft controlled manually by a human pilot, was possible.

Orville Wright was born on August 19, 1871, near Millville, Indiana, and Wilbur on April 16, 1867, in Dayton, Ohio, to Milton Wright (1828–1917), a bishop and itinerant preacher with the United

Brethren of Christ, and Susan Catherine Koerner (1831–1899), a former student of literature at Hartsville College, Indiana, with notable mechanical aptitude. They were the middle two of five siblings, which also included Reuchlin (1861–1920), Lorin (1862–1939), and Katherine (1874–1929). Their father’s job required him to travel, and on an 1878 trip he brought back with him a toy helicopter based on a design by French aeronautical pioneer Alphonse Pénaud. This has been cited as the catalyst for the brothers’ interest in aviation.

In 1885 and 1886, Wilbur’s plans to attend Yale University after high school were disrupted by an ice hockey accident: he was hit in the face by a fellow player’s stick. While his injuries healed, Wilbur slipped into depression, cancelled his plans, and withdrew to the Wright family home in Dayton, Ohio, where he spent most of his time caring for his ailing mother, who died from tuberculosis in 1889. Meanwhile, Orville dropped out of high school, more interested in such hobbies as printing, which began with access to his father’s office at the United Brethren Printing Establishment. He assumed printing as a serious hobby when the Wright family returned to Dayton to stay in 1884.

In the late 1800s, Dayton experienced unprecedented growth and economic expansion as a center of manufacturing and industry. This made it ideal for technological innovation, setting the stage for the brothers’ initial business venture. In 1889, the brothers began their first collaboration in the small printing firm Wright & Wright, with Wilbur acting as editor and Orville as publisher. They managed a number of publications, including *The Midget* (a school newspaper), Church pamphlets, bicycle catalogues, *The Dayton Tattler*, and their own newspaper, *The West Side News* (later *The Evening Item*). At this time, they began using their moniker “the Wright brothers,” by which they would be best known for the rest of their lives. They sold the business in 1899 after their mother’s death and the departure of their only regular employee, Ed Small.

They then opened the Wright Cycle Company in 1893 to capitalize on the bicycle craze sweeping the United States after two-wheeled safety bicycles were

imported from Britain. The brothers gained a reputation for their skill in manufacturing and repairing bicycles, opening their own line to meet competition in 1895. The next year, James Howard Means, an editor for *The Aeronautical Annual*, published an article describing the relationship between the speculative craft of human flight and the existing technology of bicycle mechanics. Working with this logic, the brothers applied their skill in bicycle engineering and the resources of their shop to their reemerged ambition in aeronautical pioneering.

In the 1800s, there was a widespread community of scientists and engineers investigating possible methods of controlled flight, predominantly experimenting with manned gliders. Among them were Englishmen Sir George Cayley (1773–1857), the first to systematize aeronautical research according to the scientific method; Samuel Vince, who devised the equations for lift and drag; and German Otto Lilienthal (1848–1896), who compiled the largest volume of aerodynamic data of the time. Lilienthal's death in 1896 in a gliding accident had been cited by the brothers as the catalyst to their project to build a functioning flying machine. In 1899, the Smithsonian Institution granted Wilbur's request for all of their available aeronautical data, and that same year, the brothers began testing the first *Wright Kite* at Kitty Hawk, North Carolina—chosen for its strong winds. Their breakthrough occurred in synthesizing an earlier biplane model by Octave Chanute and Augustus Herring with the concept of “wing-warping”: by twisting the wings on either side to meet the oncoming airflow at two different angles, they could generate uneven lift on either side to bank and turn the kite at will, allowing the pilot to maintain balance. Unfortunately, a series of test glides in 1901 failed to surpass a distance of 300 feet and strongly discouraged the brothers.

The brothers conducted experiments to select wing shapes in a homemade wind tunnel, where they also collected aerodynamic data that allowed them to check for faulty coefficients in Lilienthal's data as well as correct Smeaton's coefficient in the lift and drag equations. With this new data, they were able to construct a second glider in 1902, and then the famed *Wright Flyer* in 1903. The final *Flyer* had a wing area

of 500 square feet, a spruce framework with ash ribs, covered in unbleached muslin woven at a 45-degree angle to enhance wing-warping ability, and a three-axis control system of two warping wings and a rudder. An engine was custom made with parts from a Dayton foundry, with two propellers and a chain-and-sprocket transmission system. On December 17, 1903, the Wright brothers successfully conducted three rail-launched test flights of their eponymous *Flyer*, the third of which was the longest at 59 seconds and traveling 852 feet. The brothers had successfully conducted the world's first controlled flight of a power-driven aerodyne.

With skepticism of their accomplishment everywhere, Wilbur traveled to Europe, soon joined by Orville and Katherine, to demonstrate their airplane. They held audiences with royalty, including King Edward VII of England, King Alfonso XIII of Spain, and Crown Prince Friedrich Wilhelm of Germany. Upon returning to the states in 1909, they became businessmen, filling contracts for airplanes in the United States and Europe, performing flight trials for the U.S. military, and beginning the Wright Company with their first commercial airplane in 1910.

In 1912, Wilbur Wright succumbed to typhoid fever and died at the Wright family home in Dayton at age 45. Orville sold his interest in the Wright Company in 1915 and the bicycle shop in 1916, and spent his remaining years promoting aviation and consulting with government boards and commercial airlines. He died on January 27, 1948, of a heart attack at age 76.

Primary Document: Entry from Orville Wright's Diary of December 17, 1903

Reproduced here is the description of the flight of the Wright Flyer on December 17, 1903, that Orville Wright committed to his diary later that day.

Orville Wright's diary, December 17, 1903

When we got up a wind of between 20 and 25 miles was blowing from the north. We got the machine out early and put out the signal for the men at the station. Before we were quite ready, John T. Daniels, W.S. Dough, A.D. Etheridge, W.C. Brinkley of Manteo, and Johnny Moore of Nags Head arrived. After running the engine and propellers a few minutes to get them in working order, I got on the machine at 10:35 for the first trial. The wind was blowing a little over . . . 27 miles. . . . On slipping the rope the machine started off increasing in speed to probably 7 or 8 miles. . . . Mr. Daniels took a picture just as it left the tracks. I found the control of the front rudder quite difficult. . . . As a result the machine would rise suddenly to about 10 ft. and then as suddenly, on turning the rudder, dart for the ground. A sudden dart when out about 100 feet from the end of the tracks ended the flight. Time about 12 seconds (not known exactly as watch was not promptly stopped.) . . .

After repairs, at 20 min. after 11 o'clock Will made the second trial. The course was about like mine, up and down but a little longer over the ground though about the same in time. Dist. not measured but about 175 ft. . . .

At about 20 minutes till 12 o'clock I made the third trial. When out about the same distance as Will's, I met with a strong gust from the left which raised the left wing and sidled the machine off to the right in a lively manner. I immediately turned the rudder to bring the machine down and then worked the [wing-warping] control. Much to our surprise, on reaching the ground the left wing struck first,

showing the lateral control of this machine much more effective than on any of our former ones. At the time of its sidling it had raised to a height of probably 12 to 14 feet.

At just 12 o'clock Will started on the fourth and last trip. The machine started off with its ups and downs as it had before, but by the time he had gone over three or four hundred feet he had he had it under much better control, and was traveling on a fairly even course. It proceeded in this manner till it reached a small hummock out about 800 feet from the starting ways, when it began its pitching again and suddenly darted into the ground. The front rudder frame was badly broken up, but the main frame suffered none at all. The distance over the ground was 852 feet in 59 seconds. . . .

After removing the front rudder, we carried the machine back to camp. We set the machine down a few feet west of the building, and while standing about discussing the last flight, a sudden gust of wind struck the machine and started to turn it over. All rushed to stop it. Will who was near one end ran to the front, but too late to do any good. Mr. Daniels and myself seized spars at the rear, but to no purpose. The machine gradually turned over on us. Mr. Daniels, having had no experience in handling a machine of this kind, hung on to it from the inside, and as a result was knocked down and turned over and over with it as it went. His escape was miraculous, as he was in with the engine and chains. The engine legs were all broken off, the chain guides badly bent, a number of uprights, and nearly all the rear ends of the ribs were broken. One spar only was broken.

After dinner we went to Kitty Hawk to send off telegram to M.W. [Milton Wright, their father].

Yerkes Observatory

Yerkes Observatory of the University of Chicago is located at Williams Bay on Lake Geneva, in southeast Wisconsin. The 40-inch diameter telescope was

completed in 1897 and today remains the largest refracting telescope in the world. It continues to be used for solar and stellar spectroscopy and for observation of double stars. Yerkes is considered to be the birthplace of modern astrophysics.

In September 1892, George Ellery Hale (1868–1938), then a new professor of astrophysics at the University of Chicago, learned that two 42-inch blank glass disks, which had been ordered by the University of Southern California from the Parisian glassmaking firm Mantois, were for sale. Hale realized that they could be used to construct a 40-inch telescope, and he requested the University of Chicago to buy the disks.

In October Hale and university president William Rainey Harper (1856–1906) approached streetcar magnate Charles Tyson Yerkes (1837–1905) to provide funding for the new observatory. They appealed to the businessman's sense of pride by telling him that James Lick (1796–1876) would be forever remembered for the telescope he funded. Yerkes, not about to be outdone, was persuaded to make a gift to the university.

As soon as the observatory plans were announced to the public, potential donors began to compete for the building site; a total of 27 parcels of land were on offer. Hale needed to winnow down the choices, and so he took into account factors such as the effects of nearby city lights and the heating effects that traffic and bodies of water might have on the telescope's performance.

In March 1893, a university committee recommended a 53-acre parcel of land along the edge of Lake Geneva, 70 miles northwest of Chicago. In December, it was officially chosen as the site, and Yerkes hired Chicago architect Henry Ives Cobb (1859–1931) to design the observatory building. Cobb's classical design included ornate carvings, some of which depict astronomical subjects. Construction began on the cross-shaped building in 1895 and was completed in 1897. The observatory grounds were designed by landscape architect John Charles Olmsted (1852–1920).

The Massachusetts optical company Alvan Clark and Sons was chosen to prepare the glass for the telescope. Cleveland instrument manufacturer Warner and Swasey was selected to build the telescope tube and its 90-foot diameter dome.

The massive telescope mount stood 43 feet high, and the tube measured 60 feet in length. The mounting tube, sans lenses, was completed in time to be put on

The refracting telescope at Yerkes Observatory is still the largest of its kind. The 40-inch tube was first exhibited at the 1893 Chicago World's fair before being installed at the observatory. (Mondadori Portfolio via Getty Images)

display in the Manufactures and Liberal Arts Building at the Chicago Columbian Exposition, which opened in May 1893. In November a fire threatened the telescope, but it was dismantled and safely removed from the exhibit building.

The observatory was formally dedicated on October 21, 1897, at the conclusion of a three-day conference that drew astronomers and astrophysicists from around the world. The observatory's equipment included the 40-inch refractor, a 10-inch photographic telescope, and a variety of specialized equipment that included solar and stellar spectroscopes.

Yerkes was one of the first facilities to do astrophysical research as well as observation, and it has been home to many famous astronomers and astrophysicists, including Edward Barnard, Gerard Kuiper, and Frank Ross.

Hale served as the observatory's first director, and in 1895, along with astronomer James Edward Keeler (1857–1900), established the peer-reviewed *Astro-physical Journal*. Hale was succeeded by Edwin Brant Frost (1866–1935), who chaired the department from 1905 through 1932 and developed a graduate program at Yerkes.

Today Yerkes houses the 40-inch refractor, along with 24-inch and 40-inch reflecting telescopes. The observatory offers guided tours and public programs that include the opportunity for an observing session with the 40-inch refracting telescope. The building also houses a volunteer-run museum dedicated to the astronomers of Yerkes.

2. The Progressive Era and the Roaring Twenties (1900–1929)

OVERVIEW

As the United States emerged from the 19th century and all but barreled into the 20th, the country bore little resemblance to the fledgling nation that had embarked a century and a quarter before on an audacious experiment in democratic government. Its triumph in the Spanish American War signaled its arrival on the world stage, and fueled by a string of innovations and advancements that had helped establish its place among the world's economic leaders, the United States was ready to assume its new place in the world. For many Americans, this new status was simply the latest example of the Manifest Destiny that had marked the nation's progress since the early part of the 19th century, but no less critical were a series of technology-powered and science-based changes that reshaped the American economic, cultural, and political landscapes. Indeed, as the new century began, the innovative spirit and talent that had produced those changes and advances continued apace. At the same time, however, a new generation of reformers began to look for ways to harness and redirect the nation's creative power and its talents for discovery and innovation so it could serve the broader national interest and make daily life better for all Americans. Those efforts, which would include previously unimagined governmental activity, would cause the first decade and a half of the 20th century to be known as the Progressive Era.

The early days of the Progressive Era saw the crowning achievement of the nation's growing industrial might when in 1903, the nation's first billion-dollar corporation was formed with the creation of U.S. Steel. The new corporation, an exemplar of corporate innovation, was based in Carnegie Steel, a company

whose vertically integrated operations had made it the dominant force in the steel industry, and which, when merged with others to form U.S. Steel, represented the culmination of efforts by financier J. P. Morgan to achieve the most efficient way to produce the steel so central to America's industrial economy. And indeed, the creation of U.S. Steel was a corporate triumph. However, as celebrated as it was, U.S. Steel embodied the concerns of reformers who believed that the nation's industrial colossus had been built on the backs of the nation's working men, women, and children. Protecting these human cogs in the industrial machine would, over the next decade, become the focus of this era's reformers. In fact, when one thinks of science and technology as they relate to the Progressive Era, it is often in the context of the unprecedented level of governmentally administered regulatory efforts designed to tame technological advances past, present, and future. Indeed, those efforts are in many ways at the heart of the Progressive Era. But in reality, the truth lies somewhere in between. For while regulation was often necessary, regulation could not stop the ongoing advancement and innovation that had come to characterize the modern America that was emerging in the first decades of the 20th century.

Planes, Trains, and Automobiles

Nothing reflects the scientific and technological advances of the Progressive Era more fully than the automobile. On a seemingly annual basis, new inventions and innovations, large and small, were unveiled, and by the end of the Progressive Era and World War I, the horseless carriage had experienced a radical transformation in areas ranging from its production to

its appearance to what was “under the hood.” Beginning with the invention of the assembly line, a development that Henry Ford would adapt and refine in a way that ultimately revolutionized industrial production well beyond that of the automobile, the car was transformed, and it in turn transformed the nation. As Ford’s assembly line made the Model T something that was not simply a toy of the very wealthy, the increased use of the car transformed not only the way the nation traveled but also countless other aspects of American society. Indeed, many of those changes could be seen in the developments, large and small, that emerged during the Progressive Era.

Examples of these related and ultimately important developments included the 1912 invention of the traffic light, which was complemented by the development of traffic cones that same year. These had, in fact, been preceded by the development of windshield wipers. All these advances, not to mention the annual and substantial increases in road travel, made safety-based developments particularly important with the road markings, most often presented as a dividing line down the center of a road, that debuted in 1912 and the invention of the tow truck in 1913, doing much to make the driving experience safer and thus one that a driver could undertake with significantly greater confidence. Indeed, this was seen in other ways as well. Spurred by the need for better tires for an ever-increasing amount of travel, automakers drew upon Charles Goodyear’s previous work with vulcanized rubber and were able to incorporate it into the tires upon which the burgeoning auto industry rode. Too, the cars themselves got an upgrade with the development of both the automatic transmission in 1904 and, soon afterward, the automatic starter that replaced the old cranking method that was so richly satirized in the movies that were becoming an increasingly popular form of entertainment at the time.

Of course, the developments in the automotive world and especially Henry Ford’s assembly line were just one, albeit the most high-profile, area where the efficiency craze was sweeping the world of commerce. Indeed, much of the desire to invent, improve, and refine in order to achieve increased efficiency was reflective of the influence of Frederick Winslow Taylor and his theory of scientific management. Seeking

to maximize each laborer’s efforts, Taylor, utilizing his background in mechanical engineering, analyzed the labor process in a never-ending search for the most efficient way to do a job. He undertook “time and motion” studies that looked at the way in which a worker performed his or her task. He also analyzed the equipment used, an effort that at one point resulted in the designing of a shovel that allowed a worker to shovel for a longer continuous period. At the same time, Taylor believed that workers were motivated by money, and he championed the idea of “a fair day’s pay for a fair day’s work,” a concept that would reward the best workers. He also believed that certain people, in fact, worked more efficiently and effectively than others, and as a result, he urged employers to pay great attention to getting the right person for each job. From all of this research, Taylor developed four fundamental principles of scientific management, a set of beliefs that came to be known in some circles as “Taylorism.” They included a change from an accepted or habit-based approach to a job to a scientific review of the work to determine the best way to perform it; the assigning of workers to jobs based on their abilities and motivations, and to then train them so they could address the job in the most efficient way; the oversight and review workers’ performances and the provision of instruction and supervision to ensure that the most efficient ways were being utilized; and the division of labor between managers and workers so that managers could focus on training and planning to enable workers to do their jobs as efficiently as possible. For all its influence, Taylorism was not without its critics. While scientific management reflected the thoughtful, science-based problem-solving approach central to much of progressivism, critics of Taylor’s work also charged that the increasing efficiency often clashed with humanity. Such a concern was no less a part of a Progressive Era that saw the passage, at both the state and federal levels, of some of the first protective legislation aimed in particular at preventing the exploitation of workers, especially women and children.

While the Progressive Era saw a range of developments related to the automobile that would lead to a revolution in land travel, the Wright brothers’ inaugural airplane flight in December of 1903 began a process that led to a similar revolution in air travel as well as

modern warfare, with the latter change becoming very evident in World War I. Indeed, while the Wright brothers undertook continuing efforts to move their invention forward, they were joined by countless others anxious to be a part of an invention that would eventually transform American and world culture. In the end, the Progressive Era saw a raft of inventions, innovations, and new developments that would swiftly revolutionize the developing field of aviation. Among these later innovations was the first takeoff from a ship, a feat first accomplished in November 1910 by Eugene Ely, who flew from the deck of a ship anchored in Hampton Roads, Virginia, to a spot onshore. Just a few months later, in January 1911, he reversed course. Relying upon hooks that he had attached to the plane's landing gear in a significantly less sophisticated forerunner of a modern arresting gear, Ely took off from shore and landed on a ship anchored off the California coast. The ensuing years saw a wave of inventors and innovators refining and improving the basic aircraft, with their efforts leading to greater maneuverability, higher speeds, the ability to fly at higher altitudes, and greater structural strengths. These developments and more would all be tested with the advent of World War I.

Radio, Moving Pictures, and Mass Culture

Similarly, communication in the broadest sense was also undergoing some major changes as inventions, including Marconi's radio, coupled with advances in both the telephone and motion pictures, had a major impact on the nation's economic and cultural development. Radio itself, the beneficiary of continual improvements and tweaks ranging from the addition of tuners to the creation of condenser microphones that enhanced the broadcasting process, provided a whole new venue for the arts. Indeed, the first American broadcast in 1906 of voice and music ushered in a whole new chapter in popular entertainment. So quickly did things change that the U.S. government passed the first laws regulating radio in 1912. Meanwhile, at this time, entrepreneur David Sarnoff, who had begun working for a local Marconi company while still in his teens, began to first envision radio as "a household utility," and his early efforts to establish what would become the first radio network marked the

beginnings of a career that would vault him to the forefront of the American radio and television industries.

This period also witnessed major advances in film and photography, including the production of the first animated cartoons, the first color motion picture, and the earliest effort to bring sound to motion pictures. But even without sound, movies became a cultural phenomenon. *The Great Train Robbery*, released in 1904, captured the nation's imagination and ignited a hunger for action films. By 1915 full-length feature films began to appear, which only increased the nation's appetite for the new form of entertainment. These milestones were powered by technology like the replacement of the hand-cranked movie camera with a motorized version. Some of this technology was also making its way into the home, as Kodak developed the Brownie camera that made taking pictures far simpler and cheaper than ever before. Shortly thereafter, Bell and Howell developed a film projection system that would eventually make home movies a veritable American memory bank, while the development of the picture postcard during this same period created ready-made memories for travelers and tourists alike. And photographic efforts were further enhanced by the development of optical rangefinders for cameras, while the development of rotogravure helped aid the quality of magazine photos. All these new visual entertainment options were increasingly accompanied by soundtracks and musical developments that ran seemingly parallel to the visual advancements. Beyond the radio that has been discussed, there was the development of the double-sided phonograph disc as well as the first jukebox, a machine that offered 24 song possibilities. Soon the fledgling radio stations began to air voice and music productions, and in 1907, DeForest Radio began to offer regular music programming.

Wealth v. the People

The scientific and technological inventions and innovations that had fueled the nation's industrial rise at the end of the 19th century laid the foundation for this next round of scientific and technological advances. But they also encouraged—indeed, all but forced—a new set of players, the local, state, and national governments, to undertake their own form of counterinnovations in response to

the nation's ever-changing, ever-growing, innovation-inspired economy. The governmental innovations that arose in response to the technological ones were themselves an important development of the period. A government that had once been at the beck and call of the industrial titans now found itself forced to confront those same powers. The political high water mark of the Progressive Era was arguably the 1912 presidential campaign, where Theodore Roosevelt's New Nationalism and Woodrow Wilson's New Freedom offered distinct visions of how the nation's growth and development could continue—but not at the expense of the people that the government was pledged to serve. Yet these federal proposals, in fact, represented a second wave coming on the heels of efforts by innovative and dynamic state and municipal political leaders who secured the first workers' compensation laws as well as other legislation addressing the regulation of public utilities, income taxes, referendum, recall, and many others. In fact, it was only after pressure from the states, as well from as the investigative journalists known as the muckrakers, that the federal government got into the regulatory game, passing legislation creating the Food and Drug Administration, the Federal Trade Commission, and the Department of Commerce all in an effort to limit the degree to which the nation's growing industrial might would be created on the backs of the working person and the immigrants flooding into the country.

Ultimately, these efforts represented a new approach to governing, one that sought to use the power of government in creative and innovative ways in an effort to address some of the many challenges that were arising in an ever-changing United States. At the same time, in the spirit of the era, the Progressives were using the same science- and technology-based approach in their own efforts to more fully identify the nation's problems and their roots—and then design appropriate solutions to the problems. Indeed, the fruits of scientific management could yield not only more efficient ways to do a job but also safer ones. The Progressives hoped that such study could yield the one best way to do a job and reduce the ability of employers to exploit their laborers. At the same time, certain of those problems required a human response, one that lay more in innovation than in science or technology. From the work of the settlement house pioneered by

Jane Addams to the trailblazing innovative legal approach embodied in the Brandeis Brief, Progressives brought a much-needed human dimension to a previously hidebound sector of a society that was forced to confront and respond to a rapidly changing American landscape.

Big Projects and Small Inventions

On a whole different level, the Panama Canal represented another impressive advancement of the kind that could be achieved when a presidential vision fueled governmental support of the nation's impressive technological know-how. The result was an engineering marvel that altered the shape of the world—or, at the very least, humanity's ability to traverse it. Indeed, the American canal construction effort, spanning the decade from 1903 to 1914, was an engineering triumph, one that opened new economic and transportation avenues. Approximately 50 miles long and featuring three sets of locks that addressed the different elevations on the ends of the structure, construction was a herculean effort. The project was a daunting endeavor, but its completion served to transform east-west trade both within the United States and around the world.

While discussions of scientific and technological advances, inventions, and discoveries tend to focus on the developments that have had the widest impact, no less important are the seemingly smaller things, for those developments, when multiplied by the sometimes millions of people who are affected, can certainly have a huge impact on larger society. In this vein, the Progressive Era was witness to a wide range of inventions and developments that made the daily lives of many Americans considerably easier, allowing for more leisure activity and in turn changing the very face of the nation's cultural landscape. From the development of the tea bag to curtain rods to Formica, life in the American home was transformed. Too, the invention and the introduction into American homes of the radio made it possible to be entertained without leaving the comfort of one's home.

Medical discoveries, inventions, and advances were also a part of the scientific and technological developments of the era. From the development of

hearing aids to the discovery of the importance of vitamins to human health, not to mention the first blood transfusions and the invention of the electrocardiogram, new advances in knowledge and understanding helped fuel the beginnings of a transformation that saw medicine become less a wholly reactive process but instead a profession that recognized that it could, in fact, play a valuable preventive role on the road to good health.

Life for the American homeowner also underwent massive change. Not all the efficiency-based developments were done under the eye of Frederick Taylor's stopwatch. Rather, there were many efficient, new products and innovations that simply made daily life easier, often allowing individuals and families to participate in some of the other developments of the time. As noted, advances in motion pictures added a whole new dimension to popular entertainment, itself a beneficiary of the many inventions and advancements that gave the middle class large amounts of previously unimagined leisure time. Developments like the vacuum cleaner did much to enhance domestic life. Similarly, the development of the disposable safety razor was a boon to many men, while little things like the creation of the window envelope and the flashlight made life just a little bit better. And, of course, for the few who could afford it, the invention of air-conditioning in 1902 represented a godsend in the midst of summer heat. On a more fundamental level, the 1906 invention of the flushometer, a water pressure system that lowered time between toilet flushes, represented a major advance, as well as the invention of the electric dishwasher. Equally simple but no less valuable for the Progressive Era family was the development of paper towels and paper cups.

Children's lives were also changing during this period, for beyond the protective legislation that was designed to allow children to experience, at least to some degree, their childhoods, new inventions and developments brought new excitement and enrichment to their lives. Foremost among these was the creation of the Hershey bars that satisfied their sweet tooth. Beyond that, the new marvels that brightened their lives ranged from the Lionel trains that allowed them to dream of life on the rails to the soft, cuddly comfort that could be found in teddy bears. Indeed,

American children were able to find a host of new ways to enjoy some of the new-found free time that the Progressive Era began to see. Meanwhile, the introduction of the comic book offered another way to engage young imaginations. Watercoolers, not to mention popsicles and ice cream cones, were also products of this era and helped make summertime heat far more tolerable—although, as noted, the introduction of air-conditioning allowed some people to truly escape scorching summer heat.

As with so many things, the scientific and technological advances of the period represented something of a double-edged sword. Indeed, for every indisputably positive advance, whether a large one like the electric dishwasher or a smaller, simpler item like a curtain rod, coat hanger, or thumbtack, there was the more nefarious invention of an item like the gun silencer. That, of course, is the reality of change, for while American children delighted in the introduction of Lincoln Logs, Erector Sets, and Tinkertoys, not to mention Life Savers candy, the society at large could not have imagined the subsequent impact that the 1916 patent granted to Maryland civil engineer Arthur Hale for his cloverleaf interchange would have on the still fledgling auto industry and ultimately upon car travel across the United States. Meanwhile, in offices across the country, employees reveled in new, time- and cost-saving developments ranging from stenotype machines to paper shredders, from water coolers to coffee filters, to the first electric typewriters. For the homemaker, the arrival of the supermarket made life much easier, offering a full array of items all in one place, a convenience that, befitting the times, made even shopping for basic foodstuffs a more efficient process. At the same time, on the domestic side, countless numbers of families were not only able to enjoy new amounts of leisure time, but they also had their lives made easier and more comfortable by the introduction of the mixer, electric blankets—the early version had the heat coming from underneath as one lay in bed—and the shopping bag.

The Technological Challenges of Urbanization

Many of the developments and advancements of the period represented responses to the nation's changing

demographics. By 1920, for the first time in the nation's history, the majority of Americans was living in urban areas. In addition, it was during this period that, for the first time, the majority of the country's workers was in factories and not on farms. Consequently, developments that fueled this now industrial and urban-based economy had a special importance, as did some of the domestic advances that impacted the lives of the families no longer operating on a farming-focused schedule. Indeed, these shifts led to a number of important technology-based changes, including streetlights and public utilities that represented an innovative governmental foray into a previously private sector-dominated arena. In fact, expansive new urban infrastructure developed alongside transportation systems featuring trolleys and streetcars as well as the elevated railways that had begun to arrive in the late 1890s. Ultimately, there would be subways in all major cities by 1920. These developments transformed the nation's cities, allowing people to live outside the cities and commute in—offering a preview, albeit on a significantly lesser level, of the development of the suburb. Of course, improved transportation was only one area in which the cities had to adapt to accommodate their increasing populations. Developing technology allowed the cities to develop the sewer-based sanitation systems that their increased populations required, and sanitation departments, as well as professional police and fire departments, emerged in the nation's largest cities. Too, limited space, coupled with increased need, led to changes in the nation's approach to urban housing. Illustrating architect Louis Sullivan's declaration that "form follows function," stone buildings replaced wood structures, and tenements were replaced by dumbbell tenements, which were in turn replaced by apartment buildings—all of which would be dwarfed by the skyscrapers that had started to appear near the end of the 19th century but which, by the Progressive Era, had reached another level both in terms of size and their status as a testament to American engineering innovation. Whether they housed apartments or served as office buildings, the towering structures that dotted the urban landscapes, especially in the land-strapped cities stretching from Chicago to New York,

were towering monuments to America's self-declared global primacy. Despite its distinctive character, the increased urbanization of the United States was done with a bow to the country's rural roots. Indeed, growing in the shadows of the skylines in many cities was a well-developed system of public parks, with New York City's Central Park, designed by Frederick Law Olmsted, being the exemplar of what they could be. Finally, the modern cities also began to develop what might be called a commercial infrastructure for their urban residents with department stores, chain stores, and restaurants gaining a new role and popularity in city dwellers' lives.

While most of these developments set the tone for the coming decade, the Progressive Era came to an abrupt end with the United States' entry into the Great War in April 1917. Indeed, while the adoption of constitutional amendments related to both Prohibition and women's suffrage still lay ahead, as the nation went to war, the reform spirit was subsumed by the war effort, followed by the tumultuous peace. Divisions over the nation's direction in the postwar world, as well as fears of new threats from abroad, translated into the Red Scare and massive postwar labor unrest, all of which left the nation seeking stability and calm. That desire translated into the election as president of Senator Warren G. Harding. Indeed, buoyed by a resounding mandate in the 1920 contest, Harding prepared to lead the country in its "return to normalcy," one that, based on the first two decades of the 20th century, would mean a continuation of the advances in science and technology that were so much a part of the Progressive Era.

However, as the Republican administration settled in, it became clear that there would be a change in the role of government. Indeed, it was soon evident that the activist government that had characterized the Progressive Era had been replaced by a hands-off approach, one best seen in the assertion by Harding's successor, Calvin Coolidge, that "the business of America is business." Such an approach did much to reenergize the entrepreneurial spirit that had flourished in the earlier part of the century, and as a result, while in some respects the decade saw a consolidation of the earlier advances—despite the rollback of many

of the governmental innovations that had characterized the Progressive Era—the nation continued to see new inventions and advancements over the course of what would come to be known as the “Roaring Twenties.”

Nowhere was the roar louder than on the nation’s streets where the many automotive developments of the first part of the century had created a car culture that had seen the number of vehicles balloon from the 8,000 cars that had been registered in the United States in 1900 to the 9 million that were on the books by 1920. But that was only the beginning, as that number would more than triple during the 1920s, reaching 29 million by 1929. In conjunction with that growth was the development of the now much-needed traffic lights that arrived in 1920. For drivers, the 1920s saw their driving experience enhanced with the development of power steering, the introduction of the convertible, and the headrest. Meanwhile, for those lucky enough to have a garage, the development of the garage door opener offered protection from the elements once the driver arrived home. Meanwhile, in response to the still-growing car culture, the 1920s saw the opening in Dallas, Texas, of the first drive-in restaurant, an innovation that would only grow in future years.

One did not need to hit the road to benefit from the developments of the postwar era. Health-related advances included the introduction of Q-tips and Band-Aids as well as the audiometer, which helped measure hearing loss. That development was complemented by the development of the hearing aids whose need was often revealed by the device. Homeowners had their lives made easier by the introduction of the bread slicer, the garbage disposal, and the hair dryer. And, of course, the invention of the bulldozer and the pressure washer enhanced both the development and maintenance side of the ever-growing home-building industry.

With the increasing amount of leisure time that many of these developments afforded the citizens of the 1920s, people were able to enjoy new advances in entertainment and recreation. The development of waterskiing as well as sunglasses added a new dimension to life out of doors, as did the new jungle gym and monkey bars that appeared in public parks. And

of course, all of it was made better by the ice cream treat the Eskimo Pie, which debuted as the decade opened. The movie industry also continued to grow and thrive with the development of the Moviola, a device that allowed for watching and editing at the same time, enhancing the production process. But for movies, the truly big development of the 1920s was the introduction of the “talkies” with Al Jolson’s *The Jazz Singer*, premiering in 1927, being the first feature-length sound picture in cinema history. It was a revolutionary development that, like Charles Lindbergh’s transatlantic airplane flight and Babe Ruth’s record 60 home runs, both in that same year, served to reaffirm the singular American spirit that had been evident in so many ways since the turn of the century. Indeed, new advances in business, the arts, and technology—in virtually all areas of human endeavor—had left the United States in a position of unparalleled prosperity while looking to the future with unbridled optimism.

And yet, despite these unprecedented advances, the impact of which would continue to resonate for years to come, the “Roaring Twenties” would, in fact, finish with a resounding thud, marked by the stock market crash of late October 1929 that sent the nation into a financial and psychological tailspin. Indeed, for Americans, the good times that been evident on so many fronts came, suddenly and without warning, to a crashing halt as the 1920s limped into the 1930s and the once seemingly invincible nation was forced to confront an unprecedented economic reversal.

Aerosol Spray Can

Aerosol is a chemical mixture of fine solid particles that an aerosol spray can disperses by spraying the mixture into a mist of liquid particles.

The idea for aerosol spray cans can be traced to 1790 when the French began carbonating beverages. Norwegian chemical engineer Erik Rotheim of Oslo can be credited for patenting the first aerosol spray can in 1927.

The modern spray can was invented in 1941 by Americans Lyle Goodhue and William Sullivan. The American Department of Agriculture contacted the two scientists to make a more efficient and production-friendly version of Rotheim's invention. The men designed a refillable spray can intended for soldiers to kill malaria-infested bugs such as mosquitoes during World War II. The can was pressurized with liquefied gas, which gave it the ability to be sprayed with even dispersion.

In 1974, Drs. Frank Sherwood Rowland and Mario J. Molina discovered that the chlorofluorocarbons (CFCs) used in these spray cans were causing harm to the earth's ozone layer. CFCs have since been replaced with safer chemicals since the U.S. Congress passed the Clean Air Act in 1977.

In the 20th and 21st centuries, many artists used aerosol spray paint to create graffiti art.

Airplane

The airplane, which revolutionized travel, was a product of research and experimentation. Although people had always been fascinated by the idea of human flight, few believed it to be possible or practical. Over the years, innovators and inventors sought to conquer

the skies in different ways. Thanks in great part to the innovations made by Orville Wright (1871–1948) and his brother Wilbur Wright (1867–1912), motorized air travel became commonplace in the military during World War I (1914–1918) and then the public sector during the later 1940s. Airplane technology was based on old discoveries and inventions, and it led to new discoveries and inventions.

An ancient Greek myth told the story of Icarus, who made wings of feathers and wax and fell into the sea when he flew too close to the sun and his wings melted. One interpretation of the myth is that humans were not meant to fly. But flying continued to fascinate humankind. During the 15th century, Leonardo da Vinci drew sketches of impractical human-powered flying machines. His ideas, which he never experimented with physically, were almost exclusively based on his observations of nature and theory. For example, da Vinci erroneously believed that it was the flapping of wings that were the key to human flight.

The first great leap in human air travel occurred in 1782, when the Montgolfier brothers from France invented a hot air balloon that floated over Paris for 25 minutes. The Montgolfier balloon floated because the hot air inside it was lighter than the cold air around it. Although hot air balloon technology suffered from limited maneuverability, it offered humans the ability to look down from the sky for the first time. Under a hundred years later, Union forces in the American Civil War (1861–1865) sometimes used hot air balloons to collect information about Confederate troop movements.

During most of the 1800s, Europeans experimented with heavier-than-air craft with curved wings that harnessed the upward force (lift) of natural airflow. Sir George Cayley designed the first glider in the early 1800s. By the end of the 1800s, Otto Lilienthal had experienced limited success with his glider designs. Most glider flights were brief and dangerous, because the craft suffered from limited maneuverability and usually ended in crash landings. In 1896, Lilienthal died in a glider crash.

After reading about Lilienthal's death and details about his invention in the newspaper, Orville and Wilbur Wright, lifelong inventors who ran a bicycle shop with their sister Katherine, drew up a three-part

An unnamed pilot works the controls of a Wright Flyer in 1909. After inventing the airplane in 1903, brothers Orville and Wilbur Wright traveled the country demonstrating the product to potential consumers by training pilots and offering rides. Their sister Katherine often flew as a passenger to illustrate the safety of this new mode of transportation. (National Oceanic and Atmospheric Administration)

plan to design a practical flying machine. First, unlike balloons that relied on hot air to become airborne, a practical flying machine, they thought, would use the natural airflow that was already available to provide lift. Second, unlike hot air balloons and gliders that went where the wind blew them, a pilot had to be able to control the machine at all times. Third, for the craft to remain in the air for extended lengths of time, it had to be powered by an engine.

With their plan in hand, the brothers spent several years conducting research by reading books and magazines on the subject. They even borrowed books from the Smithsonian Institution in Washington, D.C. They learned about the designs of flying machines that had already been built and tried. Like da Vinci, they also observed birds in flight, and they saw how the birds

twisted their wings slightly to maintain balance. They realized that balance was a key to flying. One day while working in their bicycle shop, Wilbur got an idea while handling a long, empty box. He realized that the wings of an aircraft could be twisted in the same way as a box. Based on this realization, the brothers designed a five-foot kite with two wings (a biplane). The experiment worked. They found that by tugging at the corners of the airborne kite with ropes, they were able to twist (wing-warp) the edges of the wings and keep the kite in balance and under their control.

After the success of this model, the brothers designed a 17-foot prototype to conduct a manned experiment. The focus had primarily been on wing design instead of pilot comfort, and the design of this

plane required the pilot to lie on top of a wing. The brothers examined records of weather patterns from around the country in an attempt to find an area in the United States with steady winds. In 1900, they traveled with their prototype to Kitty Hawk, North Carolina, because it was a windy and desolate area replete with sand dunes to cushion landings. The experiments they conducted that year and the following year convinced them that the prototype design did not generate adequate lift.

They began to question the data that previous inventors had collected, and they decided to conduct their own wind tunnel experiments to simulate flying conditions. In 1902, after collecting their own flight data, the brothers returned to Kitty Hawk with a redesigned aircraft. The new machine had longer, narrower wings and a fixed tail. Lift was greatly improved, but the fixed tail made the craft less maneuverable. So they redesigned the tail to have a movable rudder. The addition was a tremendous leap forward in airplane technology. Pilots could now make the craft roll (bank so that one wing is up while the other is down), pitch (move the nose up or down), and yaw (turn the aircraft left or right). By redesigning the wings and including both wing warping and rudder controls, the brothers had achieved their first two goals in their three-part plan.

On December 17, 1903, at Kitty Hawk, Orville flew the *Flyer* with the power of a mounted light-weight engine. The airplane stayed in the air for 12 seconds and flew for 120 feet. On a fourth attempt that day, Wilbur flew for 59 seconds and reached a distance of 852 feet. In 1904, Orville flew the *Flyer II* in a complete circle around Huffman Prairie in Dayton, Ohio. After adding some more weight to the front of the *Flyer III*, in 1905, Wilbur flew for 24 miles and landed after 39 minutes of flight—but only because the engine had run out of fuel.

Having fulfilled the third part of their plan, the brothers filed for a patent for their invention and received one in 1906. The Wrights wanted to go into the business of airplane manufacturing and sales, but most of the public still had doubts about the possibility of human flight. Few had witnessed the historic first motorized flight in 1903, so the brothers made plans to expose more people to their invention. In 1909, the Wright brothers became national heroes after Wilbur

flew over New York during the Hudson-Fulton celebrations and millions of people witnessed human flight for the first time. They were introduced to kings and queens of Europe. U.S. president Howard Taft gave them an award at the White House, and their hometown hosted a carnival and a fireworks display in their honor.

As early as 1908, the U.S. and French governments showed interest in purchasing airplanes from the brothers. The Wrights built two airplanes with pilot seats included, and Orville demonstrated the invention in Washington, D.C., while Wilbur did the same in France. Unfortunately, one of Orville's demonstrations ended with the death of Lt. Thomas Selfridge, the first person to be killed in an airplane. However, the accident did not deter military interest in airplanes. In fact, during World War I, engineering and manufacturing teams greatly improved the airplane's design and capabilities. By the end of the war, American factories had produced more than 15,000 airplanes for military use. From that time, Boeing in Seattle and Washington and Lockheed in Santa Barbara, California, among others, became leading aircraft producers.

However, even though many people recognized the military uses of airplanes, in the first part of the 1900s, few civilians believed that they had practical nonmilitary uses, because they were viewed as too dangerous. In 1927, Charles Lindbergh flew his small airplane, the *Spirit of St. Louis*, safely across the Atlantic Ocean. The event transformed Lindbergh into a national hero, and it went a long way in convincing people of the airplane's viability as a mode of public transportation. The airline industry had a slow start, beginning in 1914 with one passenger.

By 1940, statistics showed that air travel was becoming safer, and the nonmilitary effects of the airplane included the creation of a mass transit system that was quicker than any other form of travel. Airlines began offering flights to different parts of the continental United States. One company, Pan American Airlines, was the first to offer international flights. Ultimately, airplane technology led to a more connected world, and advancements in airplane technology led directly to the development of jet, rocket, and space technologies.

Anderson, Mary (1866–1953)

Alabama native Mary Anderson is credited with the invention of the windshield wiper. Anderson stumbled upon this idea on a cold winter's day in New York City. Even though her invention revolutionized standard equipment in cars, she never profited from it.

Anderson was born on February 19, 1866, in Greene County, Alabama. Her father died when she reached the age of four, so she, her sister Frannie, and their mother moved to Birmingham, Alabama, and lived there until she reached the age of 27. In the early 19th century, Anderson had gone to explore New York City. On a cold day in winter, while riding in a trolley, she observed how the motorman had to completely stop the trolley, get out, and wipe away the snow manually.

When she returned to Alabama, she immediately began designing a device that would mechanically wipe the windows of motor vehicles without anyone having to get out of them. In 1903, Anderson had her model manufactured. Several companies scoffed at her invention, claiming it would only distract the driver. Her patent expired before she was ever able to market her invention.

Unsuccessful, Anderson returned home to be with her mother, sister, and brother-in-law. There, she managed the apartment building in which she lived. She died on June 27, 1953, in her summer home located in Tennessee.

Assembly Line

One of the continuing myths of American industrial history is that Henry Ford invented the assembly line. The roots of the assembly line actually go back to the Arsenal of Venice in the 1400s. Adam Smith, in his *Wealth of Nations*, had outlined the idea of labor specialization, which is basic to the assembly line. It can be said that Ford Motors made the assembly line operational and economical, but a lot of credit must go to Charles Emil Sorensen, a production genius and a loyal lieutenant of Ford. Sorensen was the mastermind behind the assembly line at Ford's Highland Park plant in Michigan. Even Sorensen, however, cannot take full credit, as it was a team of Ford managers that worked out the system.

The assembly line was created out of the crafts system as production requirements increased. Each car was originally built as a single unit by a team of mechanics. In 1910, there were over 200 manufacturers across the United States. Oldsmobile had the best factory, with a production of over 3,000 cars per year. Ford always had the dream of selling a car for the masses, but in 1910, he was bunched with all the other producers, with no cost advantage.

The Highland Park assembly line really began with the inefficiencies of the second Ford plant at Piquette Avenue, which was bigger than the first Mack Avenue plant that Ford left in 1904, but little thought, other than as to size, had been put into the layout. The cost of the 1904 Piquette plant was \$76,000. There were several buildings, requiring a lot of material and subassembly handling. The main focus at the Piquette plant was product development, which laid the groundwork

for the 1908 launch of the Model T. As noted, autos, in general, were hand built using the crafts method prior to Highland Park.

Generally, the crafts method had cars being built in stalls, with parts being brought to the car. Using the crafts system, one to two cars could be produced in a day at best. Ford's second plant at Piquette took production to over 14,000 a year, which was believed to be the limit of the crafts method. The base cost was around \$600 to \$800. Ford started to design a new plant to achieve his dream of a car for the masses. Solving the inherent problems were paramount when, in 1907, Ford started to plan the Highland Park plant to make the Model T.

Ford hired an experienced industrial architect in Albert Kahn, who had designed the 1903 Packard Motor Car Company plant in Detroit. The Highland Park plant was composed of two separate, four-story assembly buildings. The buildings were designed logically: raw materials were delivered to the top floor, and as finished parts were forged and machined, they made their way down the floors through more than 1,000 openings. Ford and Kahn had incorporated the use of gravity for chutes, conveyors, and tubes. The plant was designed to efficiently take in and distribute boxcars of supplied parts. But in 1910, the new assembly plant struggled to make 19,000 cars. It was far from an assembly line then, but it had the best materials-handling system in the world.

Even for Ford Motor Company, the assembly line was more of an evolution. Sorensen noted, "The essential tools and the final assembly line with its many integrated feeders resulted from an organization which continually used experimenting and improvising to get better production."

One key advance was the conveyor system to bring radiators to the main line. Before that, radiators had been moved by hand and muscle from the docks to the line. Gravity chute conveyance systems were designed and modeled after those in food factories such as those of Busch Beer in St. Louis and H. J. Heinz in Pittsburgh. Kahn and Ford found the gravity conveyance system so efficient that parts plants were built up to 10 stories high to take full advantage. However, Ford slowly learned that one-floor conveyor systems worked better. Conveyors started to be used for other parts and subassemblies.

Assistant superintendent Clarence Avery achieved another key advance. Experience allowed Avery to work out the timing schedules of each operation of the assembly line, which was necessary before installing conveyor assembly systems for motors, fenders, magnetos, and transmissions. Next, Ford had to standardize parts from his supply chain using blueprints. Supply chain development played a critical role in full implementation of the assembly line process. Ford Motor was able to cut manufacturing costs by 50 percent over a two-year period by implementing these types of improvements.

Ford didn't apply the integrated assembly line system until April 1913, when the company used it to build flywheel magneto assemblies for the Model T. Ford then moved to an assembly line for crankshafts. Conversion of the Highland Park plant to the assembly line method started in 1913. Prior to this, Ford had been using an intermediate phase of 50 workstations. It took an estimated 12.5 man-hours to build a car. In 1913, Ford moved the chassis to a single chain-pulled line, which cut the time to about nine man-hours. Within a year, Ford doubled production and cut the cost in half. Employment went to 13,000 in 1914 as the total investment at Highland Park went over \$200 million. The doubling of production in 1913 created a new problem, though: jobs had been specialized to the point that Adam Smith had hailed as revolutionary.

The problem was that the boring, routine work caused absenteeism to reach over 10 percent and turnover more than 300 percent! Human issues were now the limitation rather than technology. Ford's solution was to double the wage to five dollars a day, which worked. Costs came down, and the production rate hit a car every three minutes. The wage of five dollars a day did have restrictions, as Ford tried to select the best assembly workers. The requirements included that a man should be married or a woman should be the sole supporter of a family, which Ford felt was necessary for productive work. Ford also required that a person have "thrifty habits." He went as far as implementing a sociological department to monitor employees and help them develop thrift and family values. By the end of 1914, Ford had an amazing cost advantage over his competitors. He had no competition for cars priced under \$500.

Primary Document: Excerpt from Henry Ford's "The First Assembly Line" (1913)

In 1913, Henry Ford wrote an essay titled "The First Assembly Line." In the excerpt here, he describes how assembly lines could be used to build automobiles that the ordinary person could afford.

A Ford car contains about five thousand parts—that is counting screws, nuts, and all. Some of the parts are fairly bulky and others are almost the size of watch parts. In our first assembling we simply started to put a car together at a spot on the floor and workmen brought to it the parts as they were needed in exactly the same way that one builds a house. When we started to make parts it was natural to create a single department of the factory to make that part, but usually one workman performed all of the operations necessary on a small part. The rapid press of production made it necessary to devise plans of production that would avoid having the workers falling over one another . . .

The first step forward in assembly came when we began taking the work to the men instead of the men to the work. We now have two general principles in all operations—that a man shall never have to take more than one step, if possibly it can be avoided, and that no man need ever stoop over.

. . . In short, the result is this: by the aid of scientific study one man is now able to do somewhat more than four did only a comparatively few years ago. That line established the efficiency of the method and we now use it everywhere. The assembling of the motor, formerly done by one man, is now divided into eighty-four operations—those men do the work that three times their number formerly did.

Automobile Technologies (Pre–World War II)

An automobile is a wheeled passenger vehicle powered by a motor. It is designed to run on roads and generally has four wheels. The mass production automobile industry was born in the 1910s. Automobile history is often divided between the periods before and after World War II. Pre–World War II automobiles comprise a distinct stage that eventually led to the automobile revolution after the end of World War II. Automobile historians qualify the period between World War I and the Great Depression (1918–1929) as the Vintage Era. The 1930s are known as the transitional phase of the

automobile industry. From the improvements to design to the introduction of the assembly line, hydraulic brakes, the V8 engine, the fender, and more, this was a period in which automobiles went from being luxury items to common conveyances.

The earliest automobile history lies in Germany. In 1870, German Jew Siegfried Marcus designed and built the first two-cycle internal combustion engine. Ten years later, he built a four-cycle engine. In 1885, Karl Benz produced the first gasoline-powered automobile.

In 1903, Henry Ford introduced the Model A, a two-seat runabout with a two-cylinder, eight-horsepower engine that he sold for \$750. In the first decades of the 20th century, gasoline-powered engines

gradually overtook steam-powered engines, first for passenger cars and later for farm vehicles and trains.

The 1910s saw a huge expansion of different companies competing against each other. This led to a variety of automobile designs. Hudson Motor Car Company, Nash-Kelvinator Corporation, Studebaker Corporation, and Crosley Motors are just a few such companies. The 1920s was a period of immense innovation and experimentation to see what sold and what did not. This robust competition faltered at the end of the 1920s, when the stock market crash of 1929 heralded the beginning of the Great Depression.

In 1913, Henry Ford innovated the moving-chassis assembly line, allowing for automobiles to be produced at a rapid pace. This manufacturing technique made it possible to make relatively affordable cars. Ford's Model T became the first automobile to be rapidly produced using this method, becoming the car that most people could afford.

The Model T is generally seen as the true start of the automobile era. The Model T went from \$850 in 1908 to \$300 by 1925 as Ford's assembly line technology improved. As prices dropped, the number of cars sold rose. In the Vintage Era, over 15 million Model Ts were built and sold. While the Model T automobile was not particularly technologically innovative or impressive, it did allow for the mass consumption of automobiles. Although it was not until after World War II and the rise of suburbia that automobiles became seen as a necessity for most people, the popularity of automobiles began with the Model T.

Besides the assembly line, Ford is also credited with the improvement of the V8 engine. The V8 engine is an eight-cylinder combustion engine—hence the name. It allowed automobiles to go at higher speeds while running smoother than previous engines.

General Motors first started using this engine in the United States in 1916 in its Oldsmobile. The problem with the engine at the time was its price—it was too expensive to be placed into affordable cars, eventually leading General Motors to favor cheaper engines. From the start of 1922, Ford tackled making a cheaper V8 engine using his competitor's V8 engine vehicles as models. In 1932, Henry Ford introduced the first mass-produced monobloc V8 engine as an improvement to previously existing V8s. Between March and

December of that year, Ford was able to produce over 12,000 V8 engines. While it was not a perfect design, with a majority of its original versions needing fixes due to technical issues, it did eventually lead to vehicles that were able to travel much faster and cheaper than before. Much of Clyde Barrow's (of Bonnie and Clyde fame) success as a bank robber and getaway driver stemmed from the fact that he used Ford V8s while law enforcement used vehicles with smaller, slower engines.

The addition of radios into automobiles was introduced to the United States by Paul Galvin in 1930. Galvin's Manufacturing Corporation faced closure during the Great Depression, so he looked for some invention that could revitalize his business. The company invented the first car radio. Galvin could not afford to advertise, so he simply installed radios in cars and had employees drive around with the volume turned up. Galvin succeeded, and his company later was renamed Motorola—a combination of “motor vehicle” and “Victrola.” Motorola would eventually become one of America's largest communication companies.

Automobile brakes became much safer in the 1920s. The innovation of four-wheel braking mechanisms gradually became standard on most automobiles. In 1919, Malcolm Loughead invented hydraulic brakes, which became the standard at most companies, though Ford refused to switch to them at least until 1939. Hydraulic brakes are placed on each wheel so that when the brake pedal is pushed, fluid transfers to the pistons and then immediately to the brakes themselves. This system meant that automobiles could stop easier when going at top speed, an important innovation at a time when engines were becoming larger and more powerful. Beginning as a luxury car add-on, hydraulic brakes became widespread in automobiles near the end of the 1920s.

Early automobile bodies were first modeled on carriage bodies (thus the name “horseless carriage”), with fully or partially open bodies. Automobiles started to take the form of closed-body cars with a top and windows for more security and protection from the weather. By the late 1920s, almost all cars were closed body.

As closed-body cars gained popularity, the glass in the windows had to be reinforced. The first windowed automobiles turned deadly in crashes when the glass shattered, causing shards to fly all over. Innovations in

safety glass began to take shape in the 1920s. Two European inventors, Edouard Benedictus and John C. Wood, discovered a way to stop glass from shattering into pieces by creating laminated glass, or Triplex glass, named for their company established in 1923. Triplex glass was made from two pieces of glass with a resin laminated between them. Rather than splitting into a million deadly pieces, the glass would form a spider web–like pattern that we still see today in broken or cracked automobile glass. The late 1920s saw the spread of this safety glass as an add-on. It was not until 1937 that safety glass became mandatory for all car models.

Fenders on an automobile's front, rear, and side bumpers were invented in 1901 by Frederick Simms. However, it was not until the 1920s that fenders started to play a bigger role. In 1927, Harley Earl brought the notion of expanding the fenders to General Motors to allow a spare tire to be mounted on the side of a car, snugly supported on the fender itself. While Earl did not come up with the side-mounted tire first, he did refine it, placing it where it did not interfere with car doors. Major fender designs from the 1930s included the skirted fender and the “Y Job” fender, both designed by Earl. The year 1933 saw the introduction of the skirted fender, named for how it covered the wheels like a skirt. 1938 saw the Y Job automobile, with its new fender design being a part of the body, paving the way for how fenders would be designed in the postwar era.

The “Big Three” U.S. automobile makers, General Motors, Ford, and Chrysler, rose to prominence during the Great Depression in the wake of the collapse of smaller car companies. While the Big Three were not the only companies to survive the crash, they were the strongest, leading the way in innovations and sales. Many of their competitors eventually closed their doors.

From great advances in automobile technology to the growth of the major automobile companies, the Vintage Era had laid down the basis of automobiles to come. There would be only growth in the industry after World War II came to a close.

Bakelite

“Polyoxybenzylmethylenglycolanhydride,” more commonly known as Bakelite, is a material so innovative and useful that it has affected the lives of millions of people. Bakelite, a type of plastic, evolved into a seemingly infinite variety of mechanical parts, jewelry, consumer goods, packaging, construction materials, electronics, medical devices, sporting goods, and transportation and agricultural tools. Dr. Leo Hendrik Baekeland invented Bakelite in 1907.

Leo Hendrik Baekeland was born in Belgium on November 14, 1863. During his high school years, he also attended evening courses at the Ghent Municipal Technical School. In 1884, he graduated *maxima cum laude* with a doctorate in science from the University of Ghent at the age of 21. He married Celine Swarts, his professor's daughter, and they traveled to the United States in 1889. He worked as a Yonkers New York chemist for E. and H. T. Anthony and Company, manufacturers of photographic equipment, but resigned in 1893 to form Nepera Chemical Company. With his new venture, Dr. Baekeland invented a new photographic paper called Velox that could be developed with artificial gaslight. Previous versions of photo paper required indirect sunlight for development, which was inconvenient on cloudy days. The Eastman Kodak company reputedly paid Dr. Baekeland \$1 million for the Velox patent. With this new wealth, Leo and Celine purchased an estate in the New Harmony section of Yonkers, where he set up his own laboratory with an assistant, Nathaniel Thurlow.

Bakelite owes its existence to two earlier key discoveries in chemistry. In 1834, Friedlieb Ferdinand

A radio from the 1950s made from Bakelite, a synthetic resin invented in 1907 and used to make a variety of products. Bakelite fell out of use after the invention of polymer products with more practical and improved properties. (DEA/A. DAGLI ORTI/De Agostini/Getty Images)

Runge extracted phenol (C_6H_6O) from coal tar. Twenty-five years later, Alexander Mikhailovich Butlerov was the first to report on the presence of formaldehyde (CH_2O), which resulted from his attempt to synthesize methylene glycol. Later, German chemist Adolf von Baeyer and his student Werner Kleeberg conducted several experiments combining phenol with formaldehyde and reported a hard, insoluble material that ruined their laboratory equipment. At the beginning of the 20th century, several chemists were working on phenol-formaldehyde resins, but none were successful in creating a useful product.

Baekeland and Thurlow wanted to develop a synthetic resin as a substitute for shellac, a popular coating derived from the secretions of the female lac bug,

Kerria lacca. The resulting material, called Novolak, was not commercially successful. They changed the direction of their research toward finding a resin that would strengthen wood rather than simply coat it. To perform the new experiments and confirm the results, they used a specially designed steam-pressure vessel that became known as the Bakelizer. By combining phenol and formaldehyde in this vessel without a catalyst, they were able to produce a new resin that was easily moldable at high temperature and pressure but solid at room temperature. It was also highly resistant to chemical solvents, heat, and electrical current. In his laboratory notes, Leo called the new material “Bakelite.”

Leo Baekeland obtained 400 patents for the manufacture and applications of Bakelite. In 1910, he

formed a U.S. company to handle marketing and manufacturing of the material for electrical insulators. In 1930, the Bakelite Corporation occupied 128 acres in Bound Brook, New Jersey. Eventually, other plastics emerged with improved properties (e.g., more color options), but Bakelite was the first material to demonstrate the wide applicability of polymer science.

Band-Aid

Band-Aid is a brand best known for popularizing adhesive bandages, which typically consist of a square piece of gauze adhered to a strip of tape. The tape secures the gauze over a small wound to keep it sterilized and protected.

An employee of pharmaceutical giant Johnson & Johnson, Earle Dickson, created Band-Aid brand adhesive bandages in 1920. Dickson was a cotton buyer for the company. Josephine Knight, Dickson’s wife, frequently scraped her hands and arms while cleaning their house and cooking. Dickson tried to cover her wounds with gauze secured with tape, but the bandages always fell off when Knight resumed her housework. Eventually, Dickson invented what would soon become known as a Band-Aid. He cut the gauze into squares and evenly spaced them out on a roll of tape. The gauze was held in place on the tape by using crinoline. Crinoline, which is a horsehair-and-cotton blend fabric that maintains its rigidity, was commonly used to shape women’s dresses and other clothes. Dickson’s handmade adhesive bandages were a success. They kept his wife’s extremities safe from

reinjury, and she no longer required her husband’s assistance to dress her wounds.

Dickson shared his idea with his boss James Wood Johnson, who decided to mass-produce it. When Band-Aids were first introduced on the market, they failed to sell because they were handmade using the resources available in the 1920s—a time of nationwide financial stress when people could not afford to spend their money on fancier bandages. However, Johnson & Johnson continued to manufacture Band-Aid bandages and eventually created a machine to produce a more sterilized version of the previously handmade product. Sales started to rise slightly over the next decade. In 1938, a method to produce completely sterilized bandages was implemented. In 1942, the popularity of Band-Aid brand finally exploded, when millions of them were shipped overseas as part of the World War II war effort.

In a patriotic response to their new rise in sales, Johnson & Johnson introduced the first decorated adhesive bandages, known as “Stars and Strips,” in 1956. This trend of colorful bandages targeted toward the young at heart continued well into modern culture, featuring beloved designs such as Mickey Mouse, Barbie, smiley faces, Spider-Man, and Hello Kitty. Band-Aid variations have continued to come out over the following years; sports, sheer, antibiotic, and liquid bandages were all created to meet customer’s changing needs. These have been further popularized through celebrity endorsement via commercials by the likes of American icons such as John Travolta, Brooke Shields, and Teri Garr. Band-Aid has solidified itself as a household name.

Bell Telephone Laboratories

Bell Telephone Laboratories (typically referred to as Bell Labs) has achieved many technical innovations,

with the most notable being the transistor—which had numerous applications such as in telephone lines, radios, and hearing aids. The transistor developed by Bell Labs was the precursor to the complex system of transistors present on chips in modern electronics. Other advancements from Bell Labs were precursors that greatly impacted modern technology such as the first hi-fi audio recording system, films with audio tracks, silicon solar cells, fiber-optic data cables, and the first cell phone system.

Since its formation in 1925, Bell Telephone Laboratories served as a center of innovation where numerous advancements were made. The American Telephone and Telegraph Company (AT&T) established the organization as an autonomous research-and-development company complementary to the telephone company and manufacturer Western Electric, which was also a subsidiary of AT&T. Bell Labs collaborated with the other two companies to have sufficient channels of communication to efficiently control the process of design, development, and manufacturing.

For decades, Bell Laboratories was very successful. Dr. James Fisk, who was the head of Bell Labs from 1959 to 1974, attributed the success to three essential areas: people, purpose, and environment. For the laboratory to produce the best and most innovative work, it needed the best minds. It was important to recruit the finest employees, so hundreds of lab employees visited numerous colleges and universities annually to do so. The interview process was comparatively slow, taking days. Prospective employees visited the lab to meet and speak with their possible colleagues.

Leaders kept the purpose of Bell Labs broad enough to provide sufficient freedom and space for creativity; the main purpose was to innovate and improve upon areas of interest for the parent companies, AT&T and Western Electric. Employees at the lab were given a high level of autonomy where, aside from an approval process, the progress of a project was lightly monitored and employees could extend their research into long periods, even years. In addition to offering virtually unfettered access to the tools necessary for research, Bell Labs also held programs and seminars to keep employees informed of the latest

technological developments. The lab also allowed employees the freedom to publish their findings as long as they did not endanger company-held patents. The lab had its own well-respected publication: *Bell System Technical Journal*.

The environment of Bell Labs was organized so that scientists and researchers from different fields could collaborate under one roof. Many of the facilities were located in the parent companies' manufacturing plants, where scientists could convey what they had learned from their research with engineers who could use the information for practical applications. Additionally, many top scientists worked at the labs, which maintained an open-door policy so that fellow employees could seek the necessary expertise or opinion on a topic.

Binney & Smith Inc.

New Yorkers Edwin Binney and Harold Smith, inventors of the Crayola crayon, founded Binney & Smith Inc. in 1855. In 1860, Joseph Binney, Edwin's father, emigrated from England to the United States and founded Peekskill Chemical Works. The company made lampblack and ground charcoal. Edwin Binney inherited Peekskill Chemical Company from his father in 1885.

Responding to complaints that chalk was messy to write with, Binney invented a dustless chalk by mixing talc, cement, and ground slate. In 1902, he presented his chalk innovation at the St. Louis World's

fair, where he won a gold medal. The same year, he founded Binney & Smith Inc. with his cousin Harold Smith. Initially, the company produced carbon black, a substance found in gas deposits and used in printing ink, shoe polish, and black crayons.

In 1903, the company produced a “Staonal Marking Crayon” before inventing the wax markers that came to be known as crayons. Binney proved the innovator in the company, while Smith functioned as the company salesperson, promoting products that became national best sellers. Binney & Smith marketed the crayons with the brand name Crayola, a word coined by Alice Stead Binney, Edwin Binney’s wife. Crayola initially offered 18 crayon boxes of different sizes, as well as five different sizes of crayon. Initially, Binney & Smith marketed its crayons to artists. Ironically, Edwin Binney was colorblind.

In 1904, the company won another St. Louis World’s Fair gold medal, this time for crayons. As a result, the company added a gold medal to its packaging. In 1926, Binney & Smith acquired 22 new crayon colors when it acquired Munsell Color Company, which also made crayons. In 1939, Crayola combined all its crayon colors into a 52-pack of assorted crayons.

In 1958, Crayola offered a 64-color box of crayons. It contained a built-in crayon sharpener, an innovation that made the product wildly popular. In 1963, the company went public and began trading on the American Stock Exchange. Binney & Smith acquired the rights to Silly Putty, a stretchy, clay-like substance marketed for its malleability and bounce. Hallmark Cards acquired Binney & Smith in 1984. Three years later, the company added colored pencils and washable markers to its product line. In 2007, Hallmark transformed Binney & Smith into Crayola LLC.

Today, the former Binney & Smith operates production, marketing, and sales facilities in the United States, Canada, England, Germany, Australia, Italy, and Germany. In addition to crayons, colored pencils, and markers, the company produces the brands Silly Putty, Magic Marker, Liquitex, and Revell-Monogram (producer of fine scale models).

Birdseye, Clarence (1886–1956)

Inventor and businessman Clarence F. Birdseye was America’s preeminent innovator in the frozen-food industry. Birdseye discovered how to flash freeze food so that ice crystal formation caused minimal damage, creating frozen food, particularly vegetables, that more closely approximated fresh food.

Born to Ada Jane Underwood and Clarence Frank Birdseye in 1886, Birdseye was the sixth of the family’s nine children. He attended Amherst College for two years but was unable to afford the tuition to finish his degree. He dropped out of college and took a job at the U.S. Agriculture Department. He worked in New Mexico and Arizona as an assistant naturalist, supplementing his wages by trapping coyotes and selling their fur.

He also worked for noted Rocky Mountain spotted fever researcher Willard King, capturing thousands of ticks for use in King’s Hamilton, Montana, lab. In 1912, Birdseye took a job in Labrador, Newfoundland, Canada, as a fur trapper. There he had contact with local Inuit people. From these indigenous people, he learned to ice fish and observed that in below-zero weather, the fish he caught froze very quickly and, when thawed, looked and tasted like fresh fish.

He suspected that his observations of frozen fish might prove an entrepreneurial opportunity. He also thought he might be able to freeze other kinds of food, including vegetables, this way. At the time, food was generally frozen at temperatures that allowed the development of large ice crystals, which broke cell walls and caused the food to be mushy and unappetizing when thawed.

By 1922, Birdseye was conducting freezing experiments for the Clothel Refrigeration Company. Two years later, he founded Birdseye Seafood to sell flash frozen fish filets. Consumers, cognizant of the typically low quality of frozen fish, wouldn’t buy his, and the company went bankrupt. Birdseye answered this failure by developing a new method

for freezing fish, packing the filets in cartons and freezing the packages under low temperature and high pressure. This fish product proved saleable, and Birdseye's second company, General Seafood Corporation, was born.

Birdseye patented his freezing method and moved his company to Massachusetts in 1925. He also innovated machinery for his packing plant that he also patented. Four years later, he sold his company to the company that would become General Foods Corporation for \$22 million. That company developed Birds Eye frozen foods and continues to be a leader in frozen food production. Clarence Birdseye continued to work for his former company, innovating new methods for freezing food.

Over the course of Birdseye's life, he patented over 300 inventions, including a process for dehydrating food. He also pioneered the practice of leasing freezer cases to grocery store owners who could not otherwise afford the expensive machinery. Birdseye died in 1956. Today, his name is synonymous with quality frozen food.

Blender

The blender is an electric appliance that has a tall container with a small blade at the bottom of it powered by a small motor in the base. It is used for chopping, grinding, and pureeing food.

The first blender was invented in 1922 by Stephen J. Poplawski and was meant for making malts and milkshakes. In 1932, Poplawski received patents for a blender that would liquefy fruits and vegetables. In 1933, Fred Osius improved Poplawski's blender and received financing and promotion for the blender from Fred Waring, the popular musician. This blender, named the "Miracle Mixer," displayed several

technical problems, which prompted Waring to dump Osius and redesign the blender.

In 1937, Waring introduced the Waring Blender and marketed it to hotels, restaurants, and later to upscale stores such as Bloomingdale's. Waring predicted that his blender would "revolutionize American drinks," which it did. The blender is known for the preparation of cocktail drinks; however, it also became an important tool in laboratories and hospitals. Dr. Jonas Salk used the blender in his development of the polio vaccine. In 1949, Vitamix advertised "The Blender" in one of the first television infomercials.

Blodgett, Katherine (1898–1979)

Katherine Blodgett was the first woman to be awarded a doctorate in physics from the University of Cambridge. Her career at General Electric would span decades and led to the invention of "invisible glass." She also worked on improvements in glass manufacture and use in a variety of industries.

Born in 1898, Katherine grew up in Schenectady, New York—the home of the General Electric Laboratory. After her father was murdered, Blodgett spent much of her childhood in France. In 1912, she returned to New York to attend Rayson School, where her talent for mathematics and physics became evident. She attended Bryn Mawr College and later obtained her master's degree from the University of Chicago. In 1921, while at work on her masters, Blodgett published a paper describing the use of carbon filters in gas masks.

In 1926, Blodgett became the first woman to be awarded a PhD in physics from the University of Cambridge. Her work gained her the attention of

General Electric, where she was hired as the first female scientist to work for the General Electric Laboratory in Schenectady. Working in the lab under Irving Langmuir, she devised a method to spread monomolecular coatings one at a time onto glass or metal; they were later applied with a device known as the Langmuir-Blodgett trough. Her technique enabled the laboratory to produce glass that had more than 99 percent transmissivity: the first “invisible” glass through which over 99 percent of light could pass. Blodgett’s type of nonreflective coating is now known as Langmuir-Blodgett film and is widely used in cinema lens and eyeglass manufacturing. The first major cinematic production to use invisible glass was *Gone with the Wind* (1939), which was noted by critics for its crystal-clear cinematography. Langmuir-Blodgett film was also used for submarine periscopes and airplane spy cameras during World War II.

Blodgett remained with General Electric for the rest of her professional life. Throughout her career, she created numerous inventions, including the color gauge, a method to measure the molecular coatings on glass to one-millionth of an inch; poison gas absorbers; methods of deicing aircraft wings; and improvements to smokescreens used in military battles. Blodgett was issued eight patents during her career; for six of these, she was listed as sole inventor. She published over 30 papers in scientific journals, and her studies in electrical discharges laid the foundations for plasma physics.

The recipient of numerous awards, Blodgett became the first industrial scientist to receive the Francis Garvan Medal in 1951. She never married, instead living with female partners—first, Gertrude Brown, and later, Elsie Errington—in Schenectady. Blodgett was also actively involved in her community, participating in theater and civic life while pursuing interests in gardening, astronomy, antique collecting, and poetry. She died in her home in 1979.

Boeing, William E. (1881–1956)

William E. Boeing is best known for founding one of the earliest American corporations dedicated to designing, manufacturing, and selling airplanes; it eventually became a worldwide concern.

Boeing was born in 1881 in Detroit, Michigan. He attended Yale University for three years and then left without graduating in 1902 to start a lumber business in the Pacific Northwest. Around 1905, Boeing became interested in aviation, and in 1915, he learned to fly in

Los Angeles. In 1909, during an expedition in Seattle, Boeing saw a manned airplane for the first time. To pursue his interest in aviation, Boeing started off by buying a shipyard in Seattle and turned it into Pacific Aero Products Company, the first airplane factory, in 1916. His business partner, George C. Westervelt, served as a lieutenant in the U.S. Navy.

Boeing's first venture started with a small group that was working out of a combined factory and hangar space, and Pacific Aero Products earned a military contract for building ships. However, armistice was reached, so the contract was canceled. Due to the canceled contract, Pacific Aero Products faced difficult financial times; the partners were left with a lack of work. To increase revenue and escape bankruptcy, the company began experimenting, leading to the creation of a "flying boat." Originally known as the B-1, it was used to carry mail for several years between Seattle and Vancouver, British Columbia, Canada. Boeing earned one of the first international airmail contracts in 1920 for shuttling mail with the B-1 flying boat.

In 1919, Boeing completed the B&W Model 1, a single engine, two winged sea plane. Boeing offered the plane to the navy, which declined its purchase. In 1917, Boeing renamed his company Boeing Airplane Company to better represent its focus on airplanes. In 1920, the company was able to secure a manufacturing contract to build 200 Thomas-Morse MB-3 fighter planes. And in 1923, Boeing debuted the Model 40, which allowed Boeing to enter the airmail industry successfully.

During the 1920s, Boeing's Model 40, a single-engine biplane, was widely used by airmail services in the United States. In 1925, the federal Kelly Act opened airmail contracts to private companies, and in a swift move, Boeing won a contract with the redesigned Model 40A, which had air-cooled engines rather than the traditional water-cooled type. The contract required Boeing to prepare 26 airplanes by July 1, 1927, so Boeing provided a \$500,000 bond of his own personal money to expedite production. The Model 40A could not only carry mail, but also two passengers in its enclosed cabin. In 1927, to meet a government regulation, Boeing created the Boeing Air Transport (BAT), a company that transported both passengers and mail.

The Boeing Air Transport, in its first year in service, carried over 800,000 pounds of mail across the country, including 150,000 pounds of express packages. The BAT also carried nearly 2,000 passengers that year. Boeing continued to add more passenger capacity, especially through improving engines. In 1929, Boeing created the first biplane that was specifically meant only for passengers. At its debut, the Model 80 boarded 12 passengers with ease. The upgraded Model 80A could board 18 passengers on a single flight.

Prior to 1927, passengers had hardly any interest in crossing international waters in a plane until Charles A. Lindbergh crossed the Atlantic that year. Data show that in 1926, only 5,800 passengers flew, but a few years later, the number had grown to more than 400,000. This spike of interest in flying greatly benefited Boeing and allowed it to create and improve more planes. It began to assemble an industrial empire.

To improve Boeing's grasp on the aviation industry, Pacific Air Transport merged with Boeing Airplane Company and Boeing Air Transport, and the resulting firm was called United Aircraft and Transport Corporation. It offered a variety of services including civil and military aviation—particularly cargo, passenger, private, and airmail transportation.

Bottle-Making Machine

While glass bottles date back to 100 BC, they were not widely used until the process for their manufacture was automated. In 1904, Michael Owens invented the

automatic bottle-making machine, revolutionizing the container industry.

In the 1880s, a number of companies produced bottles, most with the help of glassblowing machines. The process, which relied on skilled workers, was slow, and thus the bottles were relatively expensive. In 1888, Michael Owens took a job with the Toledo Glass Factory owned by Edward Libbey. In time, Owens became the plant supervisor, all the while working on a machine that would automate bottle making. In 1903, he founded Owens Bottle Machine Company and the next year patented an automatic bottle-making machine. In his lifetime, he would patent five bottle-making or glass-shaping machines. In 1919, he partnered with Libbey to form the Owens-Illinois Glass Company, a company still manufacturing glass products today. Owens died in 1923.

The automated bottle-making machine revolutionized the soft drink and beer industries. Now with an affordable way to bottle beverages, companies inundated American consumers with a wide variety of them. Coca-Cola's iconic "hobble-skirt" bottles, for example, were a product of automated bottle making.

Bread Slicer and Wrapping Machine

A bread slicer and wrapping machine is a machine that slices and packages loaves of bread. After the bread is sliced, it travels to a packing machine. Iowan Otto Frederick Rohwedder invented the bread slicer. The world's first mechanically sliced bread went on sale July 7, 1928.

Otto Rohwedder took his machine to a struggling baker named Frank Bench in his hometown, Davenport, Iowa. After Rohwedder showed Bench how the machine worked, Bench used the machine in his bakery. Just two

weeks later, his sales had increased by 2,000 percent. Bench's customers loved the convenience of presliced bread. It was not long until more bakeries wanted Rohwedder's bread-slicing machines. Rohwedder's company, Mac-Rho, could scarcely keep up with demand. Thus began the bread-slicer-and-wrapping-machine industry, which would give rise to companies like AMF and Oliver Packing and Equipment.

Today there are many different models of bread slicer and wrapping machines, including the Saber 60 Band Slicer, Saber 75 Wide Band Slicer, Mark 60 Bread Bagger, and the Combo Bread Slicer and Bagger. AMF uses Saber Slicers and Mark Baggers because their maintenance is quick and efficient. Mark Baggers are equipped with an automated pendulum scoop drive that eliminates the cost of maintaining gearboxes that use high-friction slide action. Electronic synchronization with the bread slicer can eliminate high-maintenance chain or shaft drives. Saber Slicers have a heavy-duty stainless-steel lattice and blade guidance system for good slice quality.

Oliver Packing and Equipment Company, based in Grand Rapids, Michigan, has been manufacturing bread slicers since 1932. It is said that there are over 20,000 Oliver bread slicers that operate in North America alone. The Oliver Packing and Equipment Company has many different bread slicers, including the 2005 Compact Variable Bread Slicer, the Front Load Slicer 732, the Gravity Feed Bread Slicer 797, and many others.

Twenty-first-century consumers take sliced bread for granted, but until Rohwedder invented a bread-slicing machine, they had to slice their own bread. Mass production bread slicing creates uniform slices, and we now find it difficult to imagine bread appearing any other way. The bread-slicing machine is one of those inventions that is so integrated into American life that it is essentially invisible.

Bryant, Alice (1862–1942)

Alice Bryant was the first female surgeon to specialize in otolaryngology, a specialty in ear, nose, and throat structures. She invented and developed a variety of medical and surgical equipment for her specialty. Bryant also published more than 75 articles in her field and created evening clinics at Boston's Trinity Dispensary for those who worked during the day. In June 1914, Bryant was one of only two women among thousands of applicants who were admitted to the American College of Surgeons (ACS).

Alice Bryant was born in 1862. Bryant attended the Massachusetts Institute of Technology from 1882 through 1883, and then in 1885, she received her bachelor's degree from Vassar College. She got her medical degree in 1890 from the Women's Medical College of New York. After being accepted by the American College of Surgeons in 1914, Bryant worked at the New England Hospital for Women and Children and New England Deaconess Hospital as a medical practitioner. Bryant developed evening clinics at the Boston Trinity Dispensary for her patients' convenience so that those who worked during the day could seek out medical treatment after work had ended. This made her known for flexible hours.

Bryant developed a number of medical instruments that are used today; they became standard in the field. She developed a new tonsil tenaculum and a nasal polyp hook, which are used in tonsillectomies and the removal of nasal polyps; she also designed tonsil separators, bone-gripping forceps, and a tonsil snare cannula. The tonsil separator is a tool that has a short, beveled blade and is used to cut through the plica and mucous membrane, assisting in removing a tonsil from the surrounding tissue. The bone-gripping forceps is a clamp is used on the bone to apply compressive force during surgical procedures. One of the 75 articles that Bryant published was "The Use of the Cold Wire Snare in the Removal of Hypertrophied Tonsils," which was published by the *British Medical Journal* in November 1906.

Bryant was also part of many scientific and humanitarian organizations. In 1921, she was a member of the American Society of Heating and Ventilating Engineers, which conducted lab studies on air. Bryant, along with other doctors, joined with air-

conditioning engineers who studied the combination of air motion, humidity, and temperature to find what most people preferred. In 1924, Bryant gave a lecture on educating the hard of hearing about the value of voice training and lip reading. Bryant worked until she became sick and died on July 25, 1942.

Cannon, Annie Jump (1863–1941)

Nicknamed the "Census Taker of the Sky," Annie Jump Cannon developed the Harvard Classification Scheme in collaboration with Edward Pickering. Cannon's classification was the first to organize stars by their temperatures and spectral types, and she used it to classify more stars than any other person.

Born to Mary Jump Cannon and Wilson Cannon in 1863 in Dover, Delaware, Annie evinced an early interest in the stars. She and her mother identified stars together, observing the skies from the attic of their home. She attended Wellesley College, where she contracted scarlet fever. The disease left her partially deaf for the rest of her life, a condition that may have made socialization difficult, resulting in her immersing herself in her work. In 1884, she graduated as valedictorian with a degree in physics. She took care of her sick mother for the next 10 years, and then she returned to Wellesley to take graduate courses. She studied astronomy, spectroscopy, and photography before enrolling in Radcliffe Women's College, then the women's arm of Harvard College. Because of her age and hearing disability, she attended as a "special student" and did not earn a degree.

In 1896, Cannon joined Edward Pickering's staff of female mathematicians known as the Harvard Computers (and sometimes as "Pickering's Harem"). The lady "computers" undertook the mathematical calculations to transform astronomical observational data into material that could be entered into the Henry Draper Catalogue. Before long, Cannon was analyzing thousands of stars in order to classify them by their light spectra. She developed the now-famous OBAF-GKM classification system based on the strength of the Balmer absorption lines known to represent stellar temperatures.

At the Harvard College Observatory, as a member of the Harvard Computers, Cannon took over the work of her predecessors Nettie Farrar, Williamina Fleming, and Antonio Maury in analyzing thousands of stars. Cannon applied her own scheme to the data, developing the OBAFGKM (Oh, Be A Fine Girl, Kiss Me) classification system and the mnemonic device that has helped decades of students remember it. Cannon first published her star-cataloging system in 1901. In 1922, the system had become so accepted that the International Astronomical Union resolved to adopt it as its official star classification system.

In 1907, Cannon earned her master's degree. She continued to work with the Harvard College Observatory and went on to classify more stars than any other astronomer in history—around 350,000. She could classify three stars per minute by looking at their spectral patterns, and, using a magnifying lens, she could classify stars down to the ninth magnitude—around 16 times fainter than the human eye can see. Her findings were published in the Draper Catalogue. Cannon also discovered 300 variable stars, five novae, and one spectroscopic binary.

In 1925, Cannon earned the first honorary doctorate from Oxford University to be awarded to a woman. She also received honorary doctorates from Groningen and Oglethorpe Universities. She became the first female officer of the American Astronomical Society and the first woman to win a Henry Draper Medal (1931) for achievements in astronomy. In 1933, she attended the Chicago World's Fair as a representative of American professional women.

In 1938, Cannon was appointed to the faculty at Harvard College and named the William C. Bond

Annie Jump Cannon was the first astronomer to catalog the stars systematically, and she also discovered 277 long-period variable stars and five novae. She was the most famous female astronomer of the first half of the 20th century. (Library of Congress)

Professor of Astronomy. Although she officially retired in 1940, after more than 40 years as an astronomer, she continued to do research at the observatory.

Annie Jump Cannon died in 1941 in Cambridge, Massachusetts. Like Maria Mitchell, a mid-19th century astronomer, Cannon's achievements and contributions to professional astronomy have been largely forgotten by the American public. Nonetheless, she and Mitchell must be counted among America's greatest astronomers of any gender.

Carothers, Wallace (1896–1937)

Wallace Carothers was an inventor, chemist, and leader of organic chemistry at DuPont. Carothers developed nylon and synthetic silk, helped invent neoprene (a synthetic rubber), and derived the Carothers equation, which relates the degree of polymerization to the fractional monomer conversion. He received his PhD from the University of Illinois and received the Carr Fellowship, the most prestigious award for that university at that time for the 1923–1924 academic year. Carothers committed suicide after struggling with depression.

Carothers was born in Burlington, Iowa, on April 27, 1896. He was the oldest of four children. In his youth, he developed an interest in tools and mechanical devices. Carothers attended Tarkio College, located in Missouri, after being pressured by his father to do so. He majored in English before switching to chemistry. Carothers became a chemistry instructor before he graduated. In 1920, Carothers graduated from Tarkio College and attended the University of Illinois, where he gained his master of arts degree in 1921.

Carothers was a chemistry instructor from 1921 to 1922 at the University of South Dakota. Here he began doing independent research, which was accepted and published by the *Journal of the American Chemical Society*. Carothers's research measured the physical properties of phenyl isocyanate and of diazo benzene; he discovered that the structure of the latter compound was a chain rather than a ring.

Carothers returned to the University of Illinois, where in 1924 he received his PhD. Here he minored in mathematics and physical chemistry, specializing in organic chemistry. Carothers taught at the University of Illinois for two years in organic chemistry, and then in 1926, he moved to Harvard University, where he was an instructor of organic chemistry. In 1927, Carothers worked at DuPont's experimental station, where he researched the synthesis of polymers. Here he helped create neoprene, synthetic silk, an elastic synthetic fiber, polyamide, and last, nylon.

In 1934, Carothers drove to Baltimore to consult a psychiatrist, who enrolled him in a clinic for depression. In 1936, Carothers married Helen Sweetman. Carothers was elected to the National Academy of Science later

that year in April. By June, Carothers had been admitted to the Institute of the Pennsylvania Hospital for depression, which he had struggled with since his childhood. Eventually, Helen agreed with Carothers's doctor that she was not able to care for Carothers. His sister died of pneumonia in 1937, and later that year, Carothers committed suicide by ingesting cyanide dissolved in lemon juice—which is known to accelerate the effects of the poison. In 1982, Carothers was posthumously inducted into the Alpha Chi Sigma Hall of Fame, a professional fraternity that specializes in chemistry.

Christmas Tree Lights

For centuries, families brought life to their Christmas trees by lighting candles placed on them. Though the sight was rather pleasant, it proved to be a hazard, as many of the trees would catch on fire and cause damage to homes as well as deaths. In the late 1800s, Edward H. Johnson introduced a much safer alternative with his creation of electric Christmas tree lights. With this goal in mind, he hired Thomas Edison and eventually worked for the Edison Electric Light Company under the title of vice president. He was also the chief engineer for a system previously introduced by Edison himself.

In 1882, the public witnessed Johnson's creation. He had strung together 80 small multicolored lightbulbs to be powered simultaneously through a single cord. This proved not only much more visually pleasing than candles but much safer. As much of an improvement that it was, it still had its detriments. At the time, electricity was still foreign to the public, so Christmas lights were considered a luxury. The cost of an electrician to

wire the bulbs properly and have them all working steadily was fairly expensive—as much as \$300, about the equivalent of \$6,700 today. To address this issue, General Electric, a company founded by Edison and others in 1892, provided lights assembled as kits.

Electric Christmas tree lights gained a publicity advantage when the first electrically lit Christmas tree appeared in the White House during the administration of President Grover Cleveland in 1895. Yet, Christmas lights would not be readily available to the general public until the late 1910s. The idea of selling the lights was that of Albert Sadacca, whose family already owned a lighting company. Later innovations included blinking lights, bubble lights, icicle lights, and eventually light-emitting diode (LED) lights, which promised to save energy.

Edward H. Johnson's innovative idea of Christmas tree lights saved many lives that could have been lost if he had not had it. His idea has become a tradition that is still used over 100 years later.

Chuck Wagon

The chuck wagon was a 19th-century canvas-covered wooden wagon purposed as a mobile kitchen and invented by Charles Goodnight (1836–1929). This

precursor to modern-day catering or food trucks serviced cowboys on cattle drives across 20th-century America. Considered the most successful rancher in the early American West, Goodnight was a consummate cattleman, a Texas Ranger, pioneering cattle breeder, and designer of the first chuck wagon. At the height of his success with business partner and experienced cattleman Oliver Loving (1812–1867), their Texas million-acre cattle ranch contained over 100,000 head. The impact of the chuck wagon enabled cowboys to exist longer on the trail, far from any towns. This fueled the demand for beef and enabled the expansion of the beef industry for over two decades.

During the American Civil War (1861–1865), Texas Longhorn cattle, abandoned by owners who joined the war effort, multiplied in huge numbers—by some claims, between 3.5 and 6 million heads. Upon the end of the war, these massive herds were rounded up by "cow hunters" and claimed by enterprising ranchers. This signaled the first beginnings of the great American cattle trail drives. Those cattle not already with brands were branded with the heated iron stamp of their new owners and were spurred on by cowboys across the plains to military installations, Indian reservations, or sold, to begin a new life on a ranch or to be herded onto a train bound for the slaughterhouse. Goodnight realized that such an enormous undertaking required an equal amount of human labor able to withstand the rigors of long-distance travel over difficult terrain. An efficient system was needed to sustain this labor force, often for months at a time.

Designed in the late 1860s to early 1870s out of a Civil War surplus medical wagon, Goodnight's retooling of a wagon for wartime use to a post-wartime meal wagon sufficient to feed hungry cowboys was an innovative idea for the era. Before Goodnight's novel use of the medical wagon, cowboys carried their bedrolls under their saddles and their rations, which consisted of pork, coffee beans, salt, and sometimes cornbread, in a hand-sewn pouch attached to their saddles. With Goodnight's invention, cowboy cattle drivers were afforded a meal, a place to store personal items, rifles, and bedrolls without adding burden to their horses.

The origin of the term "chuck wagon" is likely Goodnight's repurposing of the wagon's "mess box,"

also known as a “chuck box.” The box, which fitted inside the back of the wagon, was designed with stacked drawers that acted as a larder for food and storage for cooking utensils. This mobile pantry might include dried beans, flour, and coffee along with first-aid supplies, cutlery, plates, and cups. Cast-iron pans and a Dutch oven, plus a round, cast-iron pot on three legs with a matching lid, rounded out the portable kitchen’s inventory. The typical layout of the chuck wagon included barrels of water attached to the outside, along with a toolbox and a coffee grinder. At the rear of the wagon, the chuck box sat enclosed behind a hinged, drop-down cover made of wood, which served the dual purpose of cooktop counter, propped up by a single leg.

The chuck wagon, pulled along by a team of oxen driven by a cook or Teamster, enabled cattle drives to self-sustain for long distances. When out on the plains far from home, the chuck wagon and the cook served as the social center for the life of the cowboy. Along with the business of planning, cooking, and baking meals, manners would be enforced and wounds tended to by the cook, who took on whatever contributed to a certain stability in an often harsh environment on the open trail. This cowboy protocol as dictated by the cook offered some semblance of home life: a hot meal, conversation, and a place to stow personal belongings.

Life on the open range lasted until before the turn of the 20th century. The open range herding of cattle faded as western migration continued, resulting in smaller, localized ranches and the increased use of barbed-wire fencing. With that, the purpose of the chuck wagon faded as well.

de Forest, Lee (1873–1961)

Lee de Forest, the “Father of Radio,” was an inventor who dedicated himself to media technology. Best known for his Audion, a three-element amplifying vacuum tube, de Forest was also responsible for Phonofilm, which added sound to motion pictures. De Forest held more than 180 patents, although many of his inventions were small improvements on existing technology.

De Forest was born in Council Bluffs, Iowa, to Henry Swift de Forest, a Congregational minister, and Anna Margaret Robbins. The family moved to Alabama, and de Forest was sent to the Mount Hermon School for Boys in Massachusetts. In 1893, he entered Yale University’s Sheffield Scientific School on a family scholarship and graduated with a PhD in 1899.

After graduation, de Forest worked for the Western Electric Company in Chicago on dynamos and telephone equipment. He also did experimental work in wireless telegraphy on the propagation of electromagnetic waves.

In 1902, de Forest and promoter Abraham “Abe” White formed the American DeForest Wireless Telegraph Company, with de Forest acting as the company’s scientific director. White promoted the company heavily, including building a tower at the 1904 Louisiana Purchase Exposition in St. Louis, Missouri, and operating 10 broadcast stations at the fair. However, the company ran into legal issues with stock fraud, and in November 1906 de Forest resigned.

That same month, de Forest received a patent for a two-electrode tube based on an earlier valve-like tube created by British electronics pioneer J. A. Fleming (1849–1945). Both tubes relied on something called the “Edison effect,” where electrons were observed to flow from a heated element to a cool one. Tinkering with the design, de Forest added a third wire, or grid, and named his invention the Audion. He received a patent for it in 1908 and in 1912 sold the rights to the American Telephone and Telegraph Company for use in long-distance telephony. The Audion would become a staple in radio transmission and reception.

On July 18, 1907, de Forest’s new company, the De Forest Radio Telephone Company, sent the first ship-to-shore radio broadcast. But the equipment

proved unreliable, and in 1912, the company collapsed. De Forest was prosecuted for mail fraud.

In 1920, de Forest worked with physicist Theodore Case (1888–1944) to develop a system of recording sound directly onto film. Although the system was a success, buyers were not interested, and the De Forest Phonofilm Corporation, established in 1922, shut its doors in 1926.

De Forest was elected president of the Institute of Radio Engineers in 1930. For the next 20 years, he promoted shortwave radio, despite opposing the commercialization of radio. He was bitter about his business failures and felt he had been cheated of fame and fortune. De Forest died on July 1, 1961, from a heart attack.

Dickelman, Elizabeth (dates unknown)

Elizabeth Hetzel Dickelman, better known as Lizzie, made a number of contributions to the agricultural field with her inventions and patents. Dickelman and her husband, Joseph L. Dickelman, were both a huge part of the agricultural world with her patents and their company, the Dickelman Manufacturing Co. Some of the patents under her name are for metal building plate, grain storage construction, the elastic corncrib, a grain storage bin, a ventilated grain storehouse, and the brooder house. With these patents to her name, she and her husband are considered pioneers in the agriculture field. Although many of her patents and inventions were great advancements for those in agriculture, a couple of them stand far above the rest: the corncrib and the brooder house.

A corncrib is a storage facility used in agriculture to dry and store corn; it is typically made from wood to facilitate airflow. Corncribs resemble small buildings or sheds placed high above the ground to prevent flooding and easy access for animals. Most corncribs have slits or gaps to allow air in so that the corn inside can dry properly.

Once the corn is harvested, it can be placed in a crib with or without husks. Although the principal use for the shelter is to store corn, many other crops can benefit from being placed in a corncrib—such as sunflowers, peas, beans, and tobacco.

One of Dickelman's more notable patents was one for the brooder house, also called a broiler house. It is a small insulated shelter for young animals, typically recently hatched chicks. The brooder provides them with warmth and protection. The chicks are held there until they are about six weeks old. Brooder houses are usually made of wood and are heated either by electricity or oil stoves. Brooder houses are often on the smaller side, but there are also commercial brooder houses that are large, maximizing the number of livestock being raised.

Dickerson, Mary Cynthia (1866–1923)

Mary Cynthia Dickerson was an American herpetologist and the first curator of herpetology at the American Museum of Natural History. Over the course of her lifetime, she described over 20 species of reptiles, served as editor of *The American Museum Journal*, and published numerous well-received books and articles.

Born in Michigan in March 1866, Dickerson spent her early life caring for her three younger brothers and earning money to put herself through school. She

attended the University of Michigan and earned her bachelor of science degree in 1897 from the University of Chicago. Following her studies, she taught high school biology and later became head of zoology and botany at the Rhode Island Normal School. During her tenure, she led students on nature walks and published two books: *Moths and Butterflies* (1901) and *The Frog Book* (1906). Both became popular reference books.

During the 1907–1908 school year, Dickerson served as an instructor at Stanford University, coauthoring three papers with ichthyologist David Starr Jordan to help describe the new species of halfbeak. In November 1908, she joined the American Museum of Natural History as an assistant in the Department of Woods and Forestry. Her duties included creating exhibit hall guides and developing the museum's collections, for which she amassed over 1,068 specimens and 461 species.

Dickerson's work was the catalyst for the creation of the Department of Ichthyology and Herpetology at the American Museum of Natural History, for which she became the sole herpetologist. She also served as the associate editor and then editor of *The American Museum Journal* from 1910 to 1920, overseeing the record of the museum's work, including field explorations, important acquisitions, and exhibition installations.

As curator, Dickerson instituted a tripartite effort to establish a major herpetological department consisting of exhibition work, collection building, and building a library and center for herpetological research. Unable to find time for her own investigations, Dickerson relied on young scholars who could independently conduct fieldwork and collections-based research. She recruited the museum's herpetologists—including Karl Patterson Schmidt, Gladwyn Kingsley Noble, and Charles Lewis Camp—as part of this effort.

Under her direction, the museum's herpetological collections grew to over 50,000 specimens—enough to warrant the creation of an independent Department of Herpetology in 1920. Dickerson served as the department's first curator. She considered exhibition work of equal importance to research, and she developed the concept of herpetological “habitat group” displays that employed a variety of preparation techniques, including wax casting to create lifelike models. She also described over 20 new species of reptiles, including the San Esteban chuckwalla and the Cuban sharp-nosed amphibia, and is commemorated in

the names of four lizard species: *Cnemaspis dickersonae*, *Aspidoscelis tigris dickersonae*, *Holbrookia maculate dickersonae*, and *Crotaphytus dickersonae*. Dickerson also published numerous popular and scientific articles, and she was a member of the American Academy of Arts and Sciences, American Forestry Association, American Ornithologists' Union, and the New York Academy of Sciences.

In the late 1910s, Dickerson began showing signs of mental disturbance, likely the result of stress. She became increasingly erratic and had auditory hallucinations of the Arctic explorer Vilhjalmur Stefansson, with whom she had been in correspondence on behalf of the museum. In November 1920, she was removed from the museum after a medical evaluation and placed in the care of her brother. On December 24, 1920, she was committed to a psychiatric institution on Wards Island, where she remained until her death in 1923.

Under Dickerson's lead, the herpetology section of the American Museum of Natural History had flourished, breaking new ground in the discovery and classification of amphibians and reptiles.

Drew, Charles (1904–1950)

Charles Richard Drew, known as the “Father of Blood Banks,” was born on June 3, 1904, in Washington, D.C. In his early life, Drew invented solutions for the storage and processing of blood for transfusions. Later, he managed two of the largest and best-known blood banks during World War II, which still exist to this day.

Drew was born into a middle-class family and was the eldest of five children. He showed great athletic talent during his youth, winning several medals in his elementary years in a variety of sports, including football, basketball, and swimming. Through 1918 and 1922, Drew attended Dunbar High School. He then attended Amherst College on a sports scholarship.

After completing his bachelor's degree in 1926, Drew did not have the funds to enroll in medical college, so he raised funds by working as a biology teacher and coach at Morgan College, presently known as Morgan State University. In 1928, Drew applied to several medical schools and chose to attend McGill University in Montreal, Canada. At McGill, Drew was awarded with a prize in neuroanatomy and recognized as one of the top students. In 1933, he earned degrees both as a doctor of medicine and master of surgery. Drew then did internships at Montreal General Hospital and at the Royal Victoria Hospital, when he worked closely with Dr. John Beattie to examine issues and problems pertaining to blood transfusions.

In 1938, after extensive research, Drew developed a method to preserve blood plasma (blood without cells). By separating plasma from whole blood, it can be preserved for a longer period. This research served as the basis for his doctoral thesis, and he received his degree in 1940. Drew was the first African American to receive a degree from Columbia University.

During this time, World War II was in motion, and Drew was asked to create a special medical effort known as "Blood for Britain" to collect blood to help overseas casualties. In 1941, Drew began another blood bank effort for the American Red Cross intended for U.S. military personnel. However, because of segregation, donated blood could only be used by a person of the same ethnicity as the person from whom it had originated. Due to this racist policy, Drew resigned.

After creating the first two blood banks, Drew became a professor at Howard University for the Department of Surgery, which led him to become the chief surgeon at Freedman's Hospital. Through his final years, Drew continued to be active and highly respected. He died at the age of 45 in 1950 and was continuously honored post his death by many medical colleges and schools for his contributions.

Ductile Tungsten

The development of ductile tungsten powered the revolution in electrical lighting. William D. Coolidge invented ductile tungsten in 1909.

Tungsten is a metal that provides a powerful heat resistance and has the highest melting point of all metals; therefore it is useful in very high-temperature applications. Tungsten is nonmagnetic. It is also normally very brittle but can be drawn down smaller than any other metal can; and its specific gravity is 70 percent higher than that of lead. Electric lighting innovators in the late 19th century had difficulty finding a material durable enough to function as electrical filament. In 1909, William D. Coolidge developed ductile tungsten by using powdered tungsten to create an ingot of sintered tungsten through a series of hot swagings and drawings through successively smaller dies, and with this process, bendable wire of many diameters could be made.

Ductile tungsten wire is used as an energy-efficient, high-lumen lighting filament. It has properties that contribute to increased luminosity and a long life for lightbulbs. Nearly every conventional lightbulb has a tungsten filament inside it. Tungsten spurred the rapid expansion of incandescent lamps and initiated the science of modern powder metallurgy.

Einstein, Albert (1879–1955)

A German-born theoretical physicist best known for his formulation of the special and general theories of relativity, Albert Einstein immigrated to the United States in 1933. His work provided the groundwork for the development of nuclear power and weaponry as well as the foundation for the first branch of modern

physics (the other being quantum mechanics). He won the 1921 Nobel Prize for his work on the photoelectric effect. Einstein is also known for his antiwar philosophy, caution against nuclear proliferation, and for launching the science of cosmology. He is widely regarded as the most influential physicist of the 20th century.

Albert Einstein was born on March 14, 1879, in Ulm, Württemberg, Germany to Hermann Einstein (1847–1902), a former featherbed salesman turned owner of an electrochemical factory, and Pauline Koch (1858–1920), both secular, middle-class Jews. He also had a sister, Maja (1881–1951), born two years after him. Six weeks after his birth, Einstein's family moved to Munich, where he would eventually begin elementary school at the Luitpold Gymnasium. In the late 1880s, Max Talmud, a Polish medical student and friend of the Einstein household, became an informal tutor in mathematics and philosophy to young Einstein. His inspiration to study physics began early in his life. At age five, he first encountered a compass and became fascinated with the invisible force of magnetism. At age 12, he discovered and voraciously read his first book on geometry. It is often cited that he reached a pivotal turning point at age 16, when Talmud introduced him to a series of children's science books, including one volume containing a scene imagining a race alongside the electricity in a telegraph wire. The notion of what a beam of light would look like if one traveled alongside it at the speed of light dominated young Einstein's thinking, and he produced what is considered his first scientific paper, "An Investigation on the State of the Aether in Magnetic Field."

In 1894, Einstein ran away from a Munich boardinghouse where he had been left as his father struggled with business. He felt alienated by the rigid Luitpold school system and feared impending military conscription upon coming of age, but while they were understanding, his parents feared for his prospects as a school dropout and draft dodger. He managed to enroll in the Swiss Polytechnic School in Zurich to train as a teacher in mathematics and physics. It was there that he met his future wife, Mileva Marić (1875–1948), a Serbian physics student. Upon receiving his diploma in 1901, Einstein encountered difficulty in finding teaching positions, as his habit of independent study

caused him to cut classes and alienate the professors whom he asked for letters of recommendation. He became a technical assistant at the Swiss Patent Office and gained Swiss citizenship the same year. He continued his work in theoretical physics during his spare time. He also married Marić against his parents' objections (his father gave his blessing only upon his deathbed) upon securing a steady income. The fate of their only daughter, Liserl, born before the two were married, remains a mystery.

The year 1905, in which Einstein received his doctorate, is widely regarded as his "miracle year." Einstein produced four major papers that would revolutionize physics: one was on the photoelectric effect and a second was on Brownian motion. However, he is best known for his papers on special relativity and his energy content paper that contained the famous $E = mc^2$.

His papers first came to prominence after being recognized by Max Planck, the founder of quantum theory. He began to do lecture circuits and gain increasingly prestigious academic positions. He was appointed *Privatdozent* at the University of Berne in 1908, became an associate professor of theoretical physics at the University of Zurich in 1909, assumed a similar position at the University of Prague, and finally, went to the University of Berlin to serve as director of the Kaiser Wilhelm Institute of Physics from 1913 to 1933.

In 1915, Einstein expanded special relativity to explain gravity, thus formulating his theory of general relativity: that gravity consists of the curvature of the space-time continuum. In 1921, he received the Nobel Prize for his work on the photoelectric effect.

In 1919, Einstein divorced Marić after a five-year estrangement. That same year, he married his cousin, Elsa Löwenthal (1876–1936). Elsa immigrated to the United States with her husband in 1933 and died of heart and kidney failure in 1936.

In 1933, Einstein came to the attention of the German Nationalist Socialist (Nazi) party. When his work was denounced as "Jewish physics," Einstein renounced his German citizenship and immigrated to the United States to join the Institute for Advanced Study at Princeton, New Jersey. During World War II, modifying his pacifist stance, he worked on naval

weapons systems. Einstein continued his association with the Institute for Advanced Study until his death in 1955.

While having no direct involvement with the Manhattan Project, he spurred its formation by citing concerns to President Roosevelt (1882–1945) with Leo Szilard (1898–1964) over Nazi research into atomic warfare in 1939. His mass-energy equivalency equation proved instrumental in designing the first nuclear bombs. Upon the destruction of Hiroshima, Japan, in 1945, Einstein immediately initiated the Emergency Committee of Atomic Scientists to advocate for control of nuclear weapons. While opposing research into thermonuclear warfare, Einstein did address the United Nations in an article in the *Atlantic Monthly*, espousing the idea of nuclear deterrence as a means of achieving peace.

Einstein is also known for his social work, and he joined the National Association for the Advancement of Colored People (NAACP) in the late 1940s. He joined the World Government Movement after World War II and was offered the presidency of the State of Israel, which he declined. After retiring in 1945, Einstein devoted his time and effort to constructing unified field theories that would explain the universe in a single equation. Unfortunately, Einstein largely ignored new bodies of work produced on the emerging physics of quantum mechanics, and his theories reached no applicable conclusions.

Einstein died on April 18, 1955, in Princeton at age 76. In an autopsy, it was discovered that Einstein's inferior parietal lobe, the part of the brain that processes mathematical, logical, and spatial data, was around 15 percent wider than that of the average brain.

Empire State Building

Completed almost 100 years ago, the Empire State Building stands out as a recognizable icon of New York City. The building was constructed in a city as unique as it is.

Buildings erected in the 19th century relied on load-bearing construction. The taller the building, the thicker the walls needed for support. Most buildings were no higher than six stories tall. Cities in the late 19th century saw their populations grow as more immigrants and others came to them seeking jobs. Cities with limited land, which were unable to build out, looked to build up.

Instead of building thick walls for support, James Bogardus, an iron manufacturer, built a metal frame to carry the weight of a building. Its walls, floors, and windows would rely on the cast-iron frame for support. The metal frame meant that buildings could be built safely and taller: to 16 stories.

Henry Bessemer invented a process that removed impurities from steel that produced steel that was five times stronger than iron. Steel was successfully used to construct the Brooklyn Bridge, completed in 1883.

Taller buildings, however, needed something other than stairs so people could get to the top floors. Elevators had long been used for moving freight, but the cables broke so often that they weren't safe enough to transport people. Elisha Graves Otis invented a braking system so that if its cable broke, an elevator would stop and not crash to the ground.

Tall buildings called “skyscrapers” became more common as safety measures and construction techniques improved. There were 20 buildings over 20 stories tall in New York City by 1929. The Chrysler Building was 61 stories tall. Everyone wanted to build the tallest building.

Smog obscures the view of the Chrysler Building from the Empire State Building, New York City, 1953. The American Society of Civil Engineers named the Empire State Building one of the Seven Wonders of the Modern World. (Library of Congress)

The architectural firm Shreve, Lamb & Harmon designed a building that would be 102 stories tall. The Empire State Building would be 1,250 feet from sidewalk to rooftop. The metal-frame building would have a spire at the top to serve as an anchor for the newest innovation: travel by dirigible.

The site selected was on 5th Avenue between 33rd and 34th Streets. Buildings at that location were demolished, and construction began with steel columns in concrete bases or piers. Each column weighed 44 tons. Steel beams were attached to the columns to make the frame of the building. Floors were made of concrete. Metal rivets connected the metal pieces of the frame. Brick completed the walls.

The building's exterior was done in a modern design style: Art Deco. It was of pale limestone, aluminum panes, and shiny, nickel strips placed over the brick. Sixty-seven elevators were installed inside the building, and the lobby had marble floors.

Construction lasted from early 1930 until September 1930. Workplace safety was important on such a massive project. Only six workers died on the job.

The spire for anchoring dirigibles was used only once in September 1931. The dirigible captain struggled to keep the ship steady in winds while the crew tried to deliver stacks of newspapers from it to those waiting at the top of the building. The dirigible dock was closed and not used again.

The Empire State Building was the tallest building in the world until 1972. The building was designated a National Historical Landmark in 1986 and now holds the number one spot on America's favorite architecture list.

Ford, Henry (1863–1947)

Henry Ford was the founder of Ford Motor Company. From an early age, Ford loved fixing, designing, and working with machines. Although his father wanted him to be a farmer, he devoted much of his time and energy to machines and business ventures. Even though Ford was not the first person to invent automobile technology or the assembly line, he is remembered because he perfected both. His contributions in these areas in the early 1900s helped transform the automobile from a luxury to a necessity. In later years, the automobile evolved into a permanent part of American culture. After Ford's death, his legacy as an important American industrialist, though with human flaws, was secure.

Ford was born in Springwells, Michigan, on July 30, 1863, and raised on a farm. The farm machinery fascinated him, and, due to his tinkering with it, he

became a self-taught machinist. His mother provided him with his early education, and he attended a one-room schoolhouse in the Dearborn school district in Wayne County, Michigan, during his teenage years.

Ford left home at the age of 16 and found work in Detroit, Michigan, as an apprentice for the James Flowers and Brothers Machine Shop. After learning how to manufacture valves and fire hydrants for the growing city, he terminated his apprenticeship after nine months and secured a job working with steam engines at the Detroit Dry Dock Company. From 1844 to 1885, after his long working hours, he attended business college. His pay was so low (\$10 a month) that he was forced to find other sources of income, including watch and clock repair, to pay his rent (\$14 a month).

His father was concerned about Ford's situation, and, in the hopes that his son would become a farmer, he offered him 40 acres of land next to the family farm. Ford accepted the offer, but he continued to pursue his love of working with machines. In fact, he constructed a machinist workshop on his farm—where he built his first two-cylinder internal combustion engine. During this time, he also developed his first automobile engine prototype, which weighed 500 pounds. His love of working with machines was so great that he abandoned the farm in 1891 and went to work for the Edison Illumination Company in Detroit.

Unlike his previous work in Detroit, he had professional success at his new job. As an engineer, he earned the high salary of \$100 a month. He invested much of his earnings and time to develop an internal combustion engine that could be used to propel a “horseless carriage” (soon to be known as the automobile). During his work with the Edison Illumination Company, he met Thomas Alva Edison (1847–1931), and the two men became lifelong friends. However, Ford's automobile project became so time-consuming that his boss at the Edison Illumination Company forced him to choose between his job and his project.

In 1899, Ford chose to leave the Edison Illumination Company and, with the financial backing of a wealthy businessman, established the Detroit Automobile Company. Due in part to disagreements with his investor, however, the company failed. After failing in business for a second time, in 1901, Ford raced his latest invention to victory against the fastest-known

automobiles as a publicity stunt. The publicity got businessman Alex Y. Malcomson's attention. With Malcomson's financial backing, in 1903, Ford founded the Henry Ford Company (which was later renamed Cadillac) and the Ford Motor Company. That same year, more than 1,000 other automobile companies were founded. This created a lot of competition.

Ford was able to remain successful due, in large part, to his choice of competent assistants. For example, John and Horace Dodge (the Dodge brothers) who would later go on to establish their own Dodge automobile empire, worked for Ford. In 1903, the Ford Motor Company rolled out the Model A, which sold 1,700 that year. Ford frequently introduced new models, and he assigned letters of the alphabet to each of them.

After six years of designing and building automobiles for mass consumption, Ford was able to home in on methods (including the use of standardized designs and interchangeable parts) that allowed him to make reliable, easy-to-build, and cheaply priced automobiles. He pioneered the use of the moving assembly line in his automobile factories. In this arrangement, each worker was responsible solely for the assembly of a specific part, and the automobile was built by one worker at a time as it moved along the factory line. The use of the assembly line increased production. In turn, mass production of automobiles drove costs down.

Lower-priced automobiles increased sales and profits, because more people could buy them. In 1909, Ford introduced the Model T, which became his best seller. In just one year, 8,000 of them were sold. Ford kept producing the same basic model for almost two decades and sold 34,000 in 1910, 78,000 in 1911, and 730,000 in 1916. In 1918, he appointed Edsel Ford, his son, as president of Ford Motor Company. However, Ford kept control of the company while he ran for the U.S. Senate. Although Ford was bitter over his political defeat, the Ford family business was booming, and in 1919, it opened the doors to the River Rouge (Detroit) plant, the world's largest automobile factory.

In the 1920s, millions of Americans regarded Ford a folk hero, and there was serious talk among some party leaders about nominating him as a candidate for president of the United States, but he was unable to

garner sufficient political support. By the late 1920s, competitors like General Motors and Chrysler were building automobiles that provided comfort, style, and status. As a result, Ford sales dropped dramatically. In 1927, Ford reluctantly stopped the production of the Model T. The next year, he introduced an updated Model A, but the new design failed to dominate the market like the Model T had done. To make matters worse, he lost most of his best assistants.

Ford had always been narrow-minded and stubborn, but with age, the negative side of his personality began to dominate his decisions. During the Great Depression (1929–1939), Ford refused to cooperate with President Franklin D. Roosevelt’s New Deal programs that were intended to put millions of unemployed Americans back to work. Having developed a reputation in the 1920s for paying his workers a competitive wage of five dollars a day, during the 1930s, labor leaders accused him of paying the lowest wages and maintaining the worst working conditions in the industry. Ford was willing to use violence to block union activities. When the national press criticized his actions, he either threatened to sue or sued for slander.

Perhaps the World War II era was the lowest point of Ford’s legacy. Since things were not going well for him, he believed that he was a target of a conspiracy. It was during this time that he publicized his prejudice against the Jewish people. In 1938, he garnered considerable suspicion of being a Hitler sympathizer when he accepted the Grand Service Cross of the Supreme Order of the German Eagle (the highest honor given by Germany to distinguished foreigners) from the Nazi government.

As early as the Model T era, the automobile’s importance to the economy was tremendous. Automobile manufacturing created many new jobs in various industries, including glass, rubber, steel, and textile. Workers were employed to assemble, inspect, and sell automobiles. With increasing numbers of automobiles on the road, new streets, hotels, and gas stations had to be built. The gasoline, oil, and tire industries expanded. Automobile mechanics were needed to do repairs, and so on. In short, the automobile became an important facet of the economy because it was intertwined with many other industries and professions.

“Fordism,” the term used to describe Ford’s business philosophy, involved harnessing machines, cutting costs by increasing production (economies of scale), and the constant quest for the greatest control over work steps and output. Critics charged that Fordism dehumanized workers. Principally, the use of the assembly line required workers to do machine-like (identical, repetitive, and standardized) motions. This kind of factory work environment was critically depicted in several popular motion pictures, including Charlie Chaplin’s *Modern Times* (1936).

In 1943, Edsel died, and Ford once again became the company’s president. Two years later, he relinquished complete control of his company, and Henry Ford II, his grandson, assumed the presidency. Ford died from a massive cerebral hemorrhage at his Fair Lane estate in Dearborn on April 7, 1947. His legacy as an important American innovator was secure. However, some significant events tarnished his image. Ironically, it was not until after his death that an automobile craze swept the nation, which once again brought tremendous prosperity to the Ford Motor Company.

Freon

“Freon” is a trademark name for a family of chlorofluorocarbons (CFCs). It was first synthesized by Belgian chemist Frederic Swarts. American inventor and engineer Charles Kettering and Thomas Midgley, an

engineer and chemist, led a team working for General Motors that significantly improved on CFC synthesis to create a less toxic refrigerant than ammonia.

Freon exists as a slightly toxic gas or liquid that is nonflammable. Freon is a brand name that encompasses a number of chlorofluorocarbons; however, other chlorofluorocarbons exist outside of the Freon brand, such as R-22. Chlorofluorocarbons (CFC) including Freon have been primarily used as aerosol propellants in the past but now primarily as refrigerant. The earlier versions of chlorofluorocarbons used contained chlorine and were partly responsible for depleting the ozone layer. The newer chlorofluorocarbons have changed ingredients to be more fluorine based and no longer deplete the ozone layer.

Refrigerants until 1929 relied on toxic and occasionally flammable gases such as sulfur dioxide, ammonia, and methyl chloride. During the 1920s, there were multiple reported cases of methyl chloride leaking from refrigerators and causing death due to asphyxiation. Owners of refrigerators at the time became alarmed and put them in the backyard for safety.

DuPont, Frigidaire, and General Motors worked in collaboration to find a safer means of achieving refrigeration. Thomas Midgley, with the help of Charles Kettering, invented the compound that would become known as Freon in 1928. CFCs find common use in industrial and commercial settings, aiding in refrigeration and cooling. Freon contains fluorine and carbon, which associate it with the group of aliphatic organic compounds. Freon appears colorless and nonflammable in both its liquid and gas states. CFCs are dangerous if inhaled in a sufficient amount and can cause a number of physical issues, so in many applications, an irritant is added to make detection of a leak noticeable.

In the United States, the first patent for Freon was issued to Frigidaire at the end of 1928: patent number 1,886,339. The new CFC was considered so safe that inventor Thomas Midgley demonstrated that he could inhale a lungful of the compound and exhale it onto a candle flame, proving that it was both nontoxic and nonflammable. Currently, the trademark “Freon” is owned by Chemours Company.

CFCs are no longer found in household products, such as hairspray, due to their negative effects on the

ozone layer. However, CFCs are still currently found in many products in and around the home, such as home and auto air-conditioners and refrigerators. Freon is also used in industrial refrigeration.

Galvin, Paul Vincent (1895–1959)

Paul Vincent Galvin is credited with creating the mass production process of inexpensive automotive radios. He and his brother Joseph cofounded a business that grew into the large telecommunications company Motorola, which derived its name from his first popular product: the Motorola 5T71 radio.

Born in Harvard, Illinois, on June 29, 1895, Galvin studied at the University of Illinois before being drafted into the army at the start of World War I. In 1928, Galvin and his brother started a battery eliminator (a product used to connect radios to electrical output) company and named it Galvin Manufacturing.

By 1929, with the combination of the recent stock market crash and increasing popularity of plug-in radios, Galvin Manufacturing began to fail. To remain in business, Galvin looked to the application of radios in the automotive industry. Galvin formed a team of engineers from the neighboring radio parts company to design an affordable radio that fit appropriately into an automobile dashboard.

In the development of the automotive radio, numerous issues arose, including in maintaining a strong signal and properly securing the radio inside the automobile as it was in motion. Eventually, the team developed the product far enough to have a

working prototype, which Galvin presented at an automobile convention. There he received a sufficient number of orders to continue development of the radio, allowing the company to remain financially stable.

The finished product became known as the Motorola 5T71, named by Galvin as a contraction of the term “motorized Victrola.” The product became so popular that it became synonymous with the company, which eventually legally adopted the name.

General Motors (GM)

Founded by William C. Durant and Charles S. Mott in 1908, General Motors (GM) is one of the oldest and largest automobile manufacturing companies in the world. The company once operated in 35 countries, marketing 12 brands of vehicles, including Chevrolet, Buick, Cadillac, and GMC Truck. From 1931–2007, it was the world’s leader in car sales. It withstood the Great Depression and contributed to America’s victory in World War II. GM was the first to fit cars with electric starters, eight-cylinder engines, automatic transmissions, and antilock brakes. It also brought

back electric cars. And even though it was temporarily forced into bankruptcy during the Global Recession of 2009, General Motors continues to operate both in the United States and around the globe.

GM was the collective brainchild of two Michigan horse carriage makers, William Durant and Charles Stewart Mott. In 1890, Durant founded a horseless carriage company and in 1904 became the general manager for Buick. Mott merged his company, which made bicycle wheels, with Buick. In 1908, Durant opened General Motors as a holding company and the next day acquired Buick. By 1910, Durant and General Motors also purchased Oldsmobile, Cadillac, Pontiac, and the Reliance and Rapid motor vehicle companies. Reliance and Rapid were truck makers and would become the foundation of GMC, GM’s truck division. GM also tried to buy the Ford Motor Company. Durant offered to pay \$8 million for Henry Ford’s business, potentially overextending GM’s economic capabilities. GM’s board wasn’t pleased, and Durant was fired. In 1911, Durant cofounded Chevrolet with Louis Chevrolet.

Shortly after Durant’s dismissal, GM began to issue stock. Pierre du Pont, the Delaware-based industrialist and a Durant ally, began buying up the stock to underwrite a takeover. GM’s board discovered what was happening, but it was too late. Du Pont had a majority of the shares, and Durant was returned to power. He immediately promoted du Pont to chairman of the board. Durant also added Chevrolet to the GM stable.

The presence on GM’s board of movers and shakers such as Durant, du Pont, and Charles Stewart Mott, plus a booming U.S. economy aided by the country’s involvement in World War I, not only affected GM’s bottom line but also the company’s profile. By 1918, its workforce had swollen to 85,000. Many workers had come from Southern states, a part of the country low on industry and high on unemployment. As the new workers arrived, lodging became an issue. GM spent millions on employee housing to accommodate the growing workforce. Another GM innovation was to establish a retirement system similar to what many today would recognize as a 401k. Employees donated a portion of their wages to a retirement fund, and GM matched it dollar for dollar. It also took steps to secure

its corporate future by snapping up auto parts manufacturers. By vertically integrating supply and manufacturing, Durant and the other members of GM's leadership ensured that the corporation would always have a steady stream of parts to help build its cars.

The end of World War I produced not only peace but also economic recession. Sales of cars and trucks stalled. For the second time in less than a decade, Durant was forced out. The expulsion was driven in part by Pierre du Pont, the very man who had helped underwrite Durant's return in 1916. Du Pont chose Alfred Sloan, a member of GM's board and the president of one of the parts manufacturers GM had purchased, as the company's new president. As head of GM, Sloan introduced concepts such as annual styling changes, which called for year-over-year appearance adjustments in GM products, and planned obsolescence.

Planned obsolescence was the notion of designing a product with an artificially limited window of use so that it might eventually seem unfashionable. The theory was that if annual styling changes made a new Chevrolet or Buick appear more attractive than last year's model, consumers might upgrade. Sloan also introduced a system that encouraged customer loyalty, something he termed the "ladder of success." He created a model and pricing hierarchy from Chevrolet to Pontiac to Oldsmobile, Buick, and finally Cadillac. Thus, GM could provide a car to suit every consumer's preference and price range, keeping customers' money and loyalty inside the GM family. These innovations catapulted GM into the lead among U.S. carmakers. Sloan also expanded the activities of GMAC—the General Motors Acceptance Corporation—a financial bureau within GM to provide financing to potential car owners featuring affordable monthly payments.

After weathering the Great Depression and contributing to the Allied victory in World War II, General Motors's path continued to feature expansion and innovation. It achieved the distinction of being the largest corporation in the United States. It also continued to offer new vehicle innovations such as the Corvair, America's first postwar rear-engine compact, and the Vega, a subcompact featuring an aluminum engine designed to reduce weight and increase fuel efficiency.

By the 1980s, GM was building more pickup trucks and SUVs—sport utility vehicles—a strategy that succeeded until consumers' desire for smaller, more fuel-efficient cars returned in the 21st century.

GM's most daring leap in terms of product innovation was its commitment in the 1990s to produce electric vehicles. The EV1 was the first electric vehicle to be offered by an American carmaker. It was available on a lease-only basis to consumers in targeted cities around the United States, which had established strict auto emissions standards. Although consumer reaction was favorable, GM discontinued production in 2002, citing relaxations in emission standards, the lack of available charging stations, and promising technological advances in super-low-emission, natural gas, and hybrid vehicles.

The problems that GM encountered trying to introduce electric cars were consistent with the other challenges the automaker faced in the last third of the 20th century. It responded with new products and global expansion. It found success selling cars in China and Brazil, but it also found that to succeed in other markets, it needed to be leaner and more efficient. GM reorganized when the Great Recession of 2008 struck. Cars sales plummeted, and credit evaporated. The company negotiated a bridge loan from the U.S. Treasury, but it wasn't enough, and GM filed for bankruptcy in 2009. A downsized GM emerged later that year, sporting familiar brands and a more global emphasis. Today, more than 70 percent of GM's sales come from outside the United States.

Gilbreth, Lillian (1878–1972)

Lillian Gilbreth invented the egg keeper and butter tray for inside refrigerator doors and the foot-pedal trashcan. She combined all the perspectives of an engineer, a psychologist, a wife, and a mother into her work. By applying the principles of scientific management to household tasks, Gilbreth wanted to provide women with shorter, simpler, and easier ways of doing housework to enable them to seek paid employment outside the home.

Gilbreth was born Lillian Moller in Oakland, California, the second of 11 children. She graduated from University of California, Berkeley in 1900 with a bachelor's degree in English literature and was the first female commencement speaker at the university. After finishing the first year of her PhD, she met Frank Gilbreth. The couple married on October 19, 1904. Gilbreth earned her PhD in psychology in 1915 from Brown University while also giving birth to four children. At Brown, she pioneered in industrial management.

Lillian and Frank Gilbreth applied their scientific management principles to the running of their household and a consulting businesses. The couple also wrote books together, but Lillian was left off as coauthor simply because she was a woman and could compromise their credibility despite having a doctorate. She was later described in the 1940s as “A genius in the art of living.”

Until 2005, she was the only woman awarded the prestigious Hoover Award given by five leading engineering organizations recognizing great, unselfish nontechnical services by engineers to humanity. Her work as a consultant to corporations applying psychology to solve problems in areas such as office equipment, household appliances, hospitals, and sports led her to come up with new designs and inventions to make work and life easier. She also filed patents for an improved electric can opener and the wastewater hose for clothes washers. As an industrial engineer working at General Electric, she interviewed over 4,000 women to design the proper height for stoves, sinks, and other kitchen fixtures as she worked on improving kitchen designs for modern lifestyles. While these were her most popular contributions, she

was known for having a great career while being the mother of 12 children.

Throughout Gilbreth's lifetime, she received 20 honorary degrees and also was the first female member of the Society of Industrial Engineers. A few years after retiring, she passed away, but she had proven that women could have a happy family life as well as a fulfilling and meaningful career at the same time.

Gramophone/Victrola

A gramophone or phonograph is a piece of technology capable of recording and playing sound by means of a stylus needle vibrating in grooves carved into a cylinder or disc whose rotation is powered by hand or a clockwork motor. Introduced in 1877 by American inventor Thomas A. Edison, the technology has undergone numerous transformations and changes in name. The phonograph, talking machine, Victrola, record player, hi-fi, or turntable was the predominant method of recorded music playback until the last quarter of the 20th century. By the 1930s, the rise of radio altered the technological and business dynamics for how Americans listened to music.

Due to different patents and a varied manufacturing history, the gramophone has entered into common parlance under different names, sometimes under a variety of names at the same time. The word “phonograph” was supposed to be applied only to Edison cylinder machines and was a neologism combining the Greek for “sound” (*phone*) and “writing” (*graph*). However, by the turn of the 20th century, “phonograph” was increasingly applied to any device regardless of manufacturer or type. The word “gramophone,” which originally identified Emile Berliner's flat-disc

device, was a close inversion of the word “phonograph.” This may have been done in part because “phonography” had already existed as a system of phonetic shorthand since the 1850s. “Gramophone,” “graphophone,” “phonograph,” and “zophone” were among many trademarked names often generically referred to as “talking machines.”

Despite improvements in materials and sound quality, the basic premise of the phonograph remained fairly consistent throughout its day. Sound waves were engraved on a record to move the stylus or needle up and down in a format called “hill and dale.” By the early 20th century, this was updated to allow the needle to vibrate horizontally. The movements of the needle on a record cause sound waves, which are amplified by a small tone arm vibrating a flexible diaphragm. The sound waves are then further amplified by traveling through a metal arm and horn. For much of the early history of phonographs, this horn was mounted on the exterior, giving “talking machines” their distinctive large funnels.

Victor Talking Machines devised a model that had the horn on the inside of the cabinet, which had the added benefit of volume control by opening and closing the cabinet doors. This innovation was marketed as the “Victrola,” and it soon became a common term for any phonograph with an interior horn. This type of phonograph was widespread by the 1910s and especially during the 1920s, when upper-middle-class and elite Americans could afford this expensive status symbol.

The earliest phonographs were powered by hand crank, the operator having to maintain suitable repetitive speed for the music to play consistently. As time progressed, wind-up clockwork motors were attached to the turntable to regulate speed. By the 1920s, models were introduced that used an electric motor to rotate the turntable. These electric models were often united with the expanding technology of radio to make such products as Victor Talking Machine’s “Radiola.”

Thomas A. Edison devised the first phonograph to play grooved cylinders covered in a layer of tinfoil. While Edison and other early innovators considered using flat discs in their phonographs, they rejected the idea as less efficient for the business transcription purposes they had originally intended for their invention.

The 1880s witnessed, under the guidance of Emile Berliner and Alexander Graham Bell, the use of flat discs made of wax and metal, and finally shellac. This new flat disc was more versatile and easier to reproduce on a large scale than cylinders. Played at 78 RPM (rotations per minute), these records were the ancestors in shape and format of all later record types.

The phonograph drastically transformed how Americans obtained and listened to music, plays, operas, and even the speeches of eminent persons. In the 1890s, most major cities had “phonograph parlors” where customers could request to hear music. Live performers could now record their material in a studio and have upward of 150 copies stamped on records. As copying technology improved, so too did the number of records mass-produced and placed on the market. The leading companies realized that the best way to sell phonographs was to create a line of recorded music popular with the American public.

Many contemporary “record labels” also made phonographs, including Columbia Records and Victor Talking Machines. For Victor, the color of the label determined the nature of the music: “red seal” for prestigious classical artists and “black seal” for popular music. Each company vied with the others to sign important artists that it could advertise as exclusively recording for it. The famous opera tenor Enrico Caruso was a highly sought-after performer who popularized opera and classical music in middle-class homes. Phonograph records also built the careers of great comedic acts like Van and Schenck, popular artists like Billy Murray and Al Jolson, and eminent singers like Alma Gluck and John McCormack. So long as phonograph recording was done acoustically (that is, without the aid of an electric microphone), recording artists and bands would have to crowd close to a horn and perform with a limited dynamic range.

The 1920s witnessed the rise of radio as a medium accessible to American families that could also provide a clearer performance compared to phonographs. Victor and Columbia, rivals with the greatest share in the phonograph market, struggled to maintain their supremacy. In 1925, most phonograph companies switched from acoustic to electric recordings in an effort to increase the quality and range of their product. Victor marketed these records as “orthophonic”

and released a new line of Victrolas with higher sound quality.

Improvements in recording could not recover the faltering preeminence of the phonograph companies. Edison Records folded during the Great Depression, and Victor was acquired by the Radio Corporation of America in what was seen as a sign of the changing times. The age of the talking machine had yielded to that of the radio.

Gumball Machine

Gumball machines collect coins and then dispense pieces of chewing gum usually formed into balls. The machines often include a clear sphere filled with gum-balls, and this sits on top of a metal base. A coin inserted into a slot in the base results in the gum being dispensed into a chute at the bottom of the machine. It was likely designed by Thomas Adams, who had partnered up with Antonio López de Santa Anna to make and market Mexican chicle.

The rapid growth in popularity of chewing gum led to the creation of the first gum dispenser in 1888. These machines were strategically placed in areas with a lot of foot traffic. This machine was said to be one of the first vending machines operated by coin. In 1907, the world was introduced to the first gumball machine. Not only was the shape of the dispenser different from what Adams had invented, but also the gum itself, which was spherical. The gumball machine remains a familiar sight 110 years later.

Hewitt, Peter C. (1861–1921)

American electrical engineer Peter Cooper Hewitt invented the first mercury vapor lamp in 1901. The mercury vapor lamp is a gas discharge lamp that shoots an electric arc through vaporized mercury, generally in a small tube mounted within a larger glass bulb, to produce light. The outer bulb provides both thermal insulation and protection for people, as the light produces ultraviolet radiation. Mercury vapor lamps are generally more energy efficient than both fluorescent and incandescent lights, and they have a long lifetime. They are commonly used in sports arenas, factories, warehouses, and as streetlights.

Hewitt was born in New York City in 1861 to Abram and Sarah Hewitt. He went to Stevens Institute of Technology and the Columbia University School of Mines, where he received an honorary doctorate of science. Most of his life was spent pursuing scientific innovation by using the wealth from his grandfather, Peter Cooper. Hewitt eventually realized that an electric current could pass through sealed mercury gas. His first lamps had to be started by manually tilting the tube to let the two electrodes touch in the liquid mercury. He then created an electrical ballast for his lamps to efficiently start the light. These initial lamps produced blue-green light. Hewitt solved this off-color

Electrical engineer Peter Cooper Hewitt invented the first mercury-vapor lamp in 1901. The son of a New York City Mayor, he later worked on one of the first successful precursors of the cruise missile. (Library of Congress)

light by making a transformer that added red rays of light, producing a more incandescent effect. The transformer he added produced a powerful ultraviolet light that became useful in some chemical processes, sterilization, and therapeutic practices.

Hewitt produced several other inventions, such as the first rectifier that could convert alternating current to direct current without mechanical means. Today, except for some high-power applications, it has been replaced by power semiconductor devices.

He married Lucy Work in 1887, though he later divorced her; they had no children. He married his second wife, Mary Andrews Brugiere, in 1918, and together they had one daughter, Anne Cooper Hewitt. Hewitt died in 1921, in Paris.

After Hewitt's death, the vapor lamp was improved by adding a fluorescent coating on the inside of the tube, which produced white light as it absorbed the ultraviolet light and radiation. This later led to the creation of fluorescent lights, which are low-pressure mercury vapor gas discharge lamps.

The mercury in the tube is liquid at normal temperatures, so mercury vapor lamps require a starter to heat the mercury. This process is slow and takes four to seven minutes. In addition to needing a starter, these lamps require a ballast to limit the current through them, as the lamps have negative resistance to current. If the current is not limited, the lamp will destroy itself. Mercury vapor lamps are still used commonly as streetlights, with high-pressure lamps being used in most projectors as well as in molecular spectroscopy.

Hoosier Cabinet

The Hoosier cabinet is a piece of kitchen furniture that was popular in the early 20th century, designed to provide compact storage and increased workspace for American kitchens.

In the late 1800s, the Hoosier Manufacturing Company was focused on cabinetry. Homes did not have built-in cabinetry, so the company created the Hoosier cabinet, a cupboard created in New Castle, Indiana. An existing piece of furniture, the baker's cabinet, was altered to house different compartments

of different sizes and equipped with a variety of accessories from flour jars and dispensers to spice bottles. The cabinets generally had three pieces: a base with doors on the front and drawers, a midsection that sat on the workspace and provided a shallow area for small containers, and a top compartment with doors and shelves. Cabinets also had a shelf that slid out from the cabinet itself. Some versions of the cabinet came with tea canisters, a salt box, and jars. Cards on the door interiors provided cooks with measurement conversions, and the doors were a place to keep recipes.

Since most homes are now built with furniture, the Hoosier cabinet has turned from being a necessity into a supplementary piece of furniture.

Hydroelectric Power

Hydroelectric power is an alternative method to fossil fuels, harvesting power by utilizing moving water. Facilities such as dams are the main method of harvesting energy from water. It is a renewable energy that generated 6.1 percent of power in the United States in 2015 and makes up a quarter of its total renewable energy. The International Energy Agency claims that hydroelectric power generates 16 percent of total electricity generated globally.

As early as the 12th century, there were designs for harnessing water to create energy. Al-Jazari, an engineer, wrote of several machines that used water for power, such as water mills. He developed a water supply system that distributed water to mosques and hospitals.

A surge of inventions came from the Industrial Revolution in Britain around the 18th century that used water and steam as power. One invention of the time was the water frame, which was used to make

cotton thread. Around 1712, Thomas Newcomen invented the first piston steam engine. It allowed for people to mine coal in areas that had been previously flooded. The water mill resulted in benefits to other occupations: gristmills were created to grind grain into flour. Sawmills also utilized water power to push logs through saw blades. These early methods eventually led to the use of turbines, which help produce energy for households today.

In the 19th century, the United States used water to balance heavy cargo so that it could travel inclined railroads. In the 1920s, the Federal Power Act was established to develop other hydroelectric projects. Facilities that generated power, as a result, had additional purposes such as flood control and irrigation. One example of this would be the Hoover Dam, built under the auspices of the Works Progress Administration as part of Franklin D. Roosevelt's New Deal. By 1939, the dam became the largest hydroelectricity facility in the world. On average, the dam has generated 4.2 terawatt-hours (TWh) per year since 1947 and has recently generated 3.6 TWh in 2015.

Dams like the Hoover and others not only corralled water for agricultural irrigation but created hydroelectric power. Dams brought electricity to many areas of the country for the first time, allowing people in rural and Western states to buy radios, electric lights, washing machines, and the like. However, dams also caused environmental disasters, both by depriving downstream areas of water and flooding natural areas. Many a hydroelectric dam has been immensely controversial. The Marble Canyon Dam, for example, was planned for the Colorado River, upriver from the Hoover Dam and near the Grand Canyon. Environmental and Native American activists stopped the dam from being built.

Hydroelectric power produces a fraction of the electricity that the United States consumes. In 2014, 4,146 TWh were distributed for residential, commercial, and industrial use. Corporations were created with the help of the government in the 1930s to help in the realm of energy manufacturing, which resulted in the Tennessee Valley Authority. The TVA was active in several Southeastern states and created numerous dams. Another government-owned company is the Bonneville Power Administration; in 1937, the

company was told to sell the energy it created to other companies and states.

Early U.S. hydroelectric power generators were implemented to supply lighting; however, the generators had a limit of 10 miles that power could be sent to. With further development, different methods were created to generate electricity besides with dams, which use the potential energy of the captured water. Pumped storage requires two reservoirs, one at a higher elevation than the other, with a turbine in the paths of both to create energy whenever water passes between the reservoirs. In run-of-the-river setups, there is no captured water; thus, only water flowing downstream is used to generate electricity, but there is the potential for oversupply, which leads to unused electricity. Tidal power stations use the levels of the tide that change over the course of a day to generate power.

Since hydroelectric stations are built next to bodies of water, they can produce as much energy as necessary to meet demand. Likewise, the facilities may be slowed down during periods when a surplus of power is generated. These stations emit the least greenhouse gases compared to power created from nuclear energy and fossil fuels. Since these facilities require turbines and water to fulfill their purpose, they create little pollution and are low maintenance, making them an efficient energy producer.

However, there are disadvantages to these stations. Large ones such as the Hoover Dam not only damage the ecosystem around them, but today, they are not being utilized as much. In 2014, the dam was only used when necessary, as a drought had reduced the amount of water in Lake Mead neighboring the dam. Construction costs may be too great for dams such as these to be left almost unused. The drought hurt energy production at the Hoover Dam, a particular problem in light of climate change realities. In California, years of drought have forced the use of natural gas as energy in the place of hydropower. Some areas may find themselves with an abundance of water that may not be fully utilized. The unreliability of hydroelectric power in some areas and the lack of feasibility of it in others has created a larger push for solar and wind energy.

Jacob, Mary Phelps (1891–1970)

Mary Phelps Jacob, also known as Caresse Crosby or Polly Jacob, was the first recipient of a patent for the modern bra. As fashions of the Edwardian period changed to use more loose-fitting and sheer fabrics, the era of the corset was coming to a close. Jacob was instrumental in shifting American society from the corset to her prototype of the modern bra.

Born in 1891, Jacob grew up in New Rochelle, New York. She had a privileged childhood that included private school, dancing school, and horseback-riding school. Jacob grew up in the era of the corset, a garment that sometimes narrowed an adult woman's waist to 16 or fewer inches. Corsets had been the primary means of undergarment support for women for over 350 years, but during the 1880s and 1890s, shifting fashions and cultural attitudes led to several attempts to make the corset more comfortable. This included designer Susan Taylor Converse's "Union Under-Flannel," a wool corset that had no bones, eyelets, lace, or pulleys. In 1889, Herminie Cadolle modified the corset into a two-part undergarment known as the "Well-Being," with the top half supported by the shoulders and the bottom remaining a corset for the waist and rear. And in 1893, the first brassiere had been invented by Marie Tucek in a design that included separate pockets for the breasts, shoulder straps, and hook-and-eye closures. The design never became popular.

In 1910, Jacob purchased a sheer evening gown, one of the latest fashions, for a social event. While getting ready for the event, Jacob discovered that her

corset's whalebones visibly poked out from the gown's plunging neckline and sheer fabric. Working with her maid, Jacob fashioned a prototype of the modern bra, made with two silk handkerchiefs, pink ribbon, and cord. At the social event, Jacob's new undergarment—which made wearing the sheer gown possible—was hailed by friends and family, who asked Jacob to create similar garments for them. Jacob was soon asked to produce the garment for a fee and realized that she had a potential business venture.

Jacob applied for a patent for her "brassiere" in February 1914, noting in her application that her invention provided

a garment which has no back and therefore does not interfere with any design of evening gown that may be chosen; one which is capable of universal fit to such an extent that for commercial handling it need be made in but few sizes, with reasonable certainty that the size and shape of a single garment will be suitable for a considerable variety of different customers; and . . . is characterized by extreme simplicity by freedom from bones to that it may be finished with laces or embroideries for wear beneath a sheer waist or diaphanous gown, and which when worn is both comfortable and cool and so efficient that it may be worn even by persons engaged in violent exercise such as tennis. (Jacob, 1914)

The patent was issued on November 3, 1914, for a "Backless Brassiere" that was lightweight, soft, and separated the breasts naturally. Her design did not support the breasts but rather flattened them, which suited the emerging fashions of the time. It was constructed of two pieces of cloth joined by a seam extending vertically between the breasts. The two pieces of cloth were sewn at an angle and connected around the back by tape or string supported by the shoulders and down under the arms.

Jacob opened a business in Boston, called the Fashion Form Brassiere Company, to manufacture the Backless Brassiere. She primarily employed

women in it. Her business was largely unsuccessful, though, and Jacob sold the company and her patent to Warner Brothers Corset Company for \$1,500 and moved to Europe with her husband. Jacob would never work on the bra again, instead becoming a bohemian and publisher of contemporary writers. She died in 1970.

Jacob's invention would change fashion for women during the 20th century, however. During World War I, when the U.S. War Industries Board asked women to stop buying corsets to free up metal for war production, consumer acceptance of the brassiere—nicknamed the “bra”—skyrocketed. Jacob's brassiere, now sold by Warner, enjoyed widespread use.

Kettering, Charles F. (1876–1958)

Engineer and inventor Charles Kettering was the head of research at General Motors for 27 years, founder of the Kettering Foundation, and cofounder of Delco. He held 186 patents. Some of the most important inventions he created are the electrical starting motor, leaded gasoline, the first colored paints used for mass-produced automobiles, a precursor to credit cards, the electric cash register, Freon, and the world's first aerial missile. In addition, he improved the two-stroke diesel engine by increasing the ratio of the power produced to the weight of the engine, which replaced the four-stroke diesel engine.

Kettering was born in 1876 to Jacob Kettering and Martha Hunter on a farm in Ohio. When Kettering graduated high school, he worked as a teacher. As a student, he had bad eyesight, which gave him repeated headaches, eventually forcing him to quit studying a year after he entered college. This caused him to suffer from depression. He then started working as a foreman for a telephone line for two years. In this time, he met Olive Williams, whom he would marry in 1905. Eventually, his eye problems lessened, and he was able to return to school. He graduated from Oregon State University in 1904 with a degree in electrical engineering. He was hired by National Cash Register (NCR) to work in its research lab as their electrical inventor.

While working for National Cash Register, Kettering invented an easy credit approval system. This coupled existing telephones at the sales counters with solenoid-operated stamping machines at the central office, leading to his promotion to head an inventions department. He then proceeded to invent the electric cash register, and he later improved it for restaurant use so that it could divide the total price into subcategories.

While working at NCR, Kettering used his spare time looking for ways to improve automobiles. He eventually thought of using the starter in his cash register to replace the current automobile ignition system. This would increase the battery life of cars, which at the time needed to be replaced every few hundred miles. Soon after, Kettering and NCR's general manager, Edward Deeds, founded Delco to commercialize the new ignition system, and Kettering left NCR to focus on Delco.

Kettering then started working on the electrical starting motor. He improved the electrical system, designing a starter that could be its own battery and igniter. This innovation was introduced in the Cadillac 1912 model. In the next years, Kettering sold Delco to the United Motor Company for \$2.5 million, which then became part of General Motors and the foundation for GM Research Corporation. Kettering became the head of GM Research, a vice president of GM, and a member of the GM board. When GM transferred the majority of its research to Detroit, Kettering moved with them and stayed for

the rest of his life. He continued to invent until his death in 1958.

Lie Detector

The lie detector, also known as a polygraph, is the first technological instrument developed to measure human honesty. The lie detector is based on the premise that human beings produce physiological responses when lying and that those responses can be measured to determine a person's truthfulness. While the first lie detector looked very different from modern lie detectors, the premise and the physiological responses measured remain virtually unchanged.

While there is some disagreement over who invented the first lie detector, a Berkeley police officer, John Larson, is most frequently given credit for his machine developed in 1921. Influenced by the research and work of others, Larson, with the help of a lab technician, created a detector that simultaneously recorded blood pressure and breathing. Larson's lie detector was placed on a table about six feet long. Wires connected the machine to a blood pressure cuff on the interviewee's bicep and a rubber hose that was wound around the chest to measure the depth of breathing. The interviewee was instructed to sit still so that the machine would accurately record the person's physiological responses. Once the machine was turned on, the black recording paper began to turn, and two needles scratched the blood pressure and respiration measurements onto the paper. Then, Larson was ready to begin questioning. Larson devised a combination of relevant and irrelevant questions that required only yes and no answers. This combination helped to determine the person's truthfulness.

Several problems with Larson's lie detector were immediately apparent. First, it was extremely large

and not easy to transport. Second, the pressure cuff only permitted the interview to last six minutes before it became painful. Third, the results on the black recording paper were blurry and difficult to preserve. Finally, the transfer of information from the rubber tubes to the pens was unreliable and not very sensitive.

A number of improvements were made to Larson's lie detector. In the early 1930s, Leonarde Keeler (1903–1949) patented the Keeler Polygraph, the first portable polygraph that addressed many of the problems in Larson's lie detector. Keeler also added an additional testing component: perspiration (sweat). Over time, pneumatic sensors, which relied on air pressure, were replaced with electronic sensors, and these were eventually replaced by computerized sensors. In the 1990s, the scrolling paper was replaced by computer screens. Computerized algorithms were created to help the examiner interpret the results. In 2012, the American Polygraph Association began requiring a fourth measurement, which would record body movement as a countermeasure to "beating the machine."

While Larson invented the lie detector as a tool for police investigations, the courts have continuously denied their use in the courtroom. Banned from court proceedings, polygraph examiners found numerous other places for their machines to be useful. William Marston (1893–1947), who also introduced Wonder Woman to Americans in 1942, and Keeler were instrumental in introducing the lie detector to almost every aspect of American society. Marston envisioned a world where families might use home lie detectors to resolve disputes or women might test the honesty of potential husbands.

By the middle of the 20th century, millions of polygraph examinations were taking place each year. Law enforcement used the lie detector to streamline their investigations. Banks, department stores, insurance companies, and government agencies used it in employee hiring and investigations. Eventually, the machine went beyond determining truthfulness and was used to determine who could be trusted, to determine political loyalty, to eliminate petty theft, and to eliminate the third degree in investigations. Controversy over the increased use of the lie detector led to

the Employee Polygraph Protection Act of 1988, which led to a decrease in the number of tests conducted, especially in the private sector; however, exceptions continue to allow many tests to be conducted.

The lie detector continues to be an important technological invention in American society, although its successes and the American fascination with it have led to an increase in research to identify what other physiological responses are connected to lying and what machines we can use to identify truthfulness. In the 1960s, research began to focus on voice stress analysis, which detects changes in voice and tone. Since then, lasers have been used to detect muscular, circulatory, and other bodily changes. Facial thermal imaging identifies blood flow pooling around the eyes, and functional magnetic resonance imaging (fMRI) examines changes in the brain when a person lies. Despite all of these other tools, the lie detector first invented by Larson continues to be the most widely used form of lie detection.

Life Savers Candy

Life Savers brand hard candies were created in 1912 by Clarence Crane (1875–1931). A longtime business owner, Crane wanted to make a new type of candy that would not melt in summer heat. He had experience working with sweets, having owned a company that produced maple sugar. After experimenting with

various forms of hard candy, he developed the formula for Life Savers. He produced the candies by using a machine that made tablets and punching out a hole in the middle, thereby creating the distinctive life preserver shape that gave the Life Savers their name. He called them "Pep-O-Mint Life Savers," packed them in a cardboard tube, and marketed them as breath mints. Sales of Life Savers surged once the candies were marketed to bar owners for use by customers who wanted to mask the smell of alcohol and cigarettes.

Today, Life Savers brand candies are sold around the world and include fruit flavors, gummy textures, and even sour varieties.

Marsh, Albert L. (1877–1944)

Albert Leroy Marsh, an American metallurgist, coined the alloy known as "nichrome." Composed of nickel, chromium, iron, and other trace elements, this metallic alloy was primarily used in the creation of heating elements. Due to its high electrical resistance and durability under high temperatures—which consequently yields a great amount of heat—the alloy, typically melded into the form of a wire, can be found as a safe igniter for fireworks, a blade for a hot wire cutter, or even as part of daily life tools such as toasters and hair dryers.

Born in August 16, 1877, Marsh was the eldest of three; he grew up in Pontiac, Illinois, but shortly moved with his family to Pana, Illinois. In 1901, Marsh graduated from the University of Illinois at Urbana-Champaign with a bachelor's degree in chemical engineering.

Marsh's eventual success with the nichrome alloy began as simple experimentation with alloys

of nickel and chromium on the side of his main work. In need of a place to work on his experiments, he was hired by William Hoskins, co-owner of the leading firm in chemistry known as Mariner & Hoskins.

While working for Mariner & Hoskins, Marsh created an alloy a few hundred times stronger than any others on the market. Dubbed originally “chromel,” the initial composition of the alloy was 80 percent nickel and 20 percent chromium. Marsh patented the alloy in 1906 but soon after sold the patent to Hoskins’s company, which had been renamed as Hoskins Manufacturing. His newfound success led him to a promotion as both a chief engineer and a general manager of the firm, and later in 1915, he became the president of Hoskins Manufacturing.

After the creation of the alloy, the company sought to apply it in its untapped market, which eventually led to the creation of the chromel wire. Most other metals used for conducting wires in the market required manufacturing into thin, fragile wires to create enough resistance to generate heat. Because the chromel wire did not have to rely on this—due to its high electrical resistance property—the wire was much sturdier than any other at the time. Thus, the company’s primary focus became the production of these wires.

Nichrome is widely used. Because the alloy produces heat when given an electrical surge, 21st-century manufacturers have used it as part of ignition systems for objects such as electric matches, fireworks, and igniters for model rockets. The wire is also typically used in ceramics as a support for the clay; its durability in intense heat allows the wire to support a sculpture while in the kiln. The alloy has been used to make heating coils for various appliances ranging from toaster ovens to some motorcycle mufflers to electronic cigarettes.

McKnight, William L. (1887–1978)

American businessman William L. McKnight’s career led him to the top of the 3M Company. During his later years, he became a philanthropist, creating the McKnight Foundation with his wife, Maude L. McKnight, in 1953.

William L. McKnight began his life on a South Dakota homestead on November 11, 1887. His parents were Joseph and Cordelia McKnight, who came to South Dakota seven years prior to build their homestead. McKnight attended Duluth Business University. Upon his graduation in 1907, he gained employment as an assistant bookkeeper for 3M. His starting salary at 3M was \$11.55 a week.

3M was a struggling company on the edge of bankruptcy when McKnight started his career there. During his early years of employment, he was known for his insistent ideas about creating better products and cutting costs. His forward thinking gained the attention of his general manager, who promoted McKnight to cost accountant. Within two years of his first promotion, McKnight was offered his first opportunity in a leadership position when he was placed in charge of 3M’s Chicago office. McKnight’s next promotion came in 1914 when, at the age of 27, he moved to St. Paul and took over as the general manager at 3M’s headquarter office. It would only take McKnight two short years before he advanced to 3M’s vice president at the age of 29 in 1916. In 1929, McKnight, at the age of 42, took over for Edgar Ober as president of the company as the latter became too ill to carry on.

Under McKnight’s management, 3M went from a struggling mineral processing company to a multinational technology manufacturing company. The company began manufacturing sandpaper in 1921, and masking tape and the now-famous “Scotch Tape” in 1925. These products stabilized the company. In 1947, 3M began processing chemicals, allowing it to expand its business to Canada, Mexico, and Europe.

McKnight would hold the position of president for 20 years until 1949, when he was appointed chairman of the board. He held that position until 1966, at which point he was relieved and given the title of honorary chairman of the board until 1972. During his career

with 3M, McKnight was recognized as having saved the company from the brink of bankruptcy and turning it into a multinational corporation with his emphasis on research and development and employee innovation.

McKnight also created the McKnight Foundation with his wife, Maude L. McKnight, in 1953 in Minneapolis, Minnesota. The McKnight Foundation has no ties to the 3M Company. McKnight spent 59 years working for his private philanthropic organization, running it alongside his wife until shortly after her death, at which point he passed on its leadership to Virginia McKnight, their only child. Under her guidance, the foundation began offering community grants in Minnesota and still does so today.

William L. McKnight's hobbies included Thoroughbred horse racing; he owned Tartan Farm, a breeding center in Ocala, Florida. McKnight owned the award-winning horses Dr. Patches, Ta Wee, Dr. Fager, and the horse Intentionally, who won the Futurity Stakes by setting a track record time. McKnight's horses are known for winning the Eclipse award.

On March 4, 1978, William L. McKnight died at age 90. Seventeen years after his death, the Junior Achievement U.S. Business inducted McKnight into their hall of fame for businessmen. McKnight was recognized for his contribution to changing the culture of corporations by emphasizing that management should delegate tasks and encourage employee imitative and innovation; many of his contributions to business are still in practice today at 3M.

Midgley, Thomas (1889–1944)

American inventor and chemist Thomas Midgley is best known for inventing leaded gasoline and chlorofluorocarbons (CFCs).

Born in Beaver Falls, Pennsylvania, in 1889, Midgley spent his childhood in Columbus, Ohio. After graduating from Cornell University in 1911, Midgley worked briefly at National Cash Register (NCR), where he met the inventor and entrepreneur Charles Kettering. Midgley worked in his family business before going to work at Kettering's Dayton Engineering in 1916.

Kettering assigned Midgley to solve the problem of "knock," a tendency of early combustion engines to begin shaking violently at high power. Part of this was due to early piston design, and part was due to the low-octane gasoline available at the time. Midgley experimented with various fuel additives before discovering tetraethyl lead in 1921.

From the beginning, Midgley and other researchers were concerned about the effects that lead would have on the public. Midgley was hospitalized for lead poisoning shortly before leaded gasoline was first offered for sale on February 1, 1923, and six workers producing tetraethyl lead died of lead poisoning the following year. Public outcry and a 1925 hearing led by the U.S. surgeon general raised awareness, but General Motors and other corporate interests quashed concerns over the harmful effects of leaded gasoline. Leaded gasoline allowed the development of more powerful engines and larger vehicles, although catalytic refining techniques developed a decade later would eventually allow high-octane fuels to replace leaded gasoline.

In 1928, Kettering took charge of GM's research department and assigned Midgley to solve the problem of refrigerants. Within a day, Midgley and his assistants deduced that a fluorine compound would meet the requirements of a refrigerant (which had to expand quickly from a liquid to a gas, absorbing heat from the surrounding area) without the toxicity problems of ammonia and other common refrigerants. By

the end of the day, they had begun testing on chlorofluorocarbons (CFCs). The compound R-12 (later called Freon) was unveiled in 1930, and by the decade's end, it was in worldwide use in air-conditioners and refrigerators. CFCs later became popular industrial solvents and cleaners; this is how much of the CFC in the atmosphere escaped.

Midgley began researching synthetic rubber, but his research slowed dramatically after he came down with polio in 1940. He was paralyzed from the waist down. In 1944, he was elected president of the American Chemical Society; shortly afterward, he either was accidentally strangled in the ropes that allowed him to move around his bedroom or committed suicide.

Midgley's inventions made a dramatic difference in the world, for good—his fuel additives jump-started the development of airplanes and automobiles, and Freon saved countless people from food poisoning or spoiled medicines—and for bad, because the additives were toxic to the environment and humans. Midgley died before the discovery in the 1970s that CFCs were destroying the ozone layer and before the revelations of health problems that led to the 1986 ban on leaded gasoline in the United States.

Morgan, Garrett (1877–1963)

Garrett Morgan invented the a hair straightener, a safety hood that later inspired a similar device used in World War I, and an improved traffic signal that increased safety on American roadways.

Garrett Morgan was born on March 4, 1877, in Paris, Kentucky. His mother was Elizabeth Reed

Morgan, who was half Native American, and he was half African American. His father was Sydney Morgan, a former slave that was freed in 1863. With only an elementary school education, Morgan moved to Cincinnati, Ohio, at age 14 to find a job. He became a handyman for a landowner. In 1895, he moved to Cleveland, where he started work as a sewing machine repairman. In 1907, he opened his own repair shop business. A year later, he married Mary Anne Hassek and had three sons.

In 1909, Morgan and his wife opened a tailoring shop. While working at his shop, Morgan developed his first invention: hair-straightening gel. Morgan noticed that sewing machine needles would leave scorch marks on fabrics because of friction. He experimented with some chemical solutions and created a solution that reduced the friction. He tested this solution on his own hair and found that it stood up straight. He had just stumbled upon the first hair straightener. Morgan then established the G. A. Morgan Hair Refining Company to sell his product in 1913.

After witnessing a traffic accident at an intersection involving an automobile and a horse wagon, Morgan received a patent for an improved traffic signal from the U.S. Patent Office on November 20, 1923. At the time, there were only stop and go signals in the United States. Morgan's upgraded traffic signal consisted of a T-shaped pole with an additional signal: a yield sign. He had created a warning signal that would tell cars that they needed to slow to a stop. It was an equivalent of the yellow light in today's traffic light. This sign stopped traffic from all directions to let pedestrians cross. This important improvement decreased the number of car accidents at intersections and increased the safety of drivers and pedestrians. He eventually sold his patent to General Electric for \$40,000.

In 1914, Morgan invented a breathing device called the "safety hood." Morgan was inspired to make a breathing device because he had witnessed firefighters struggling to breathe in the overwhelming amount of smoke and gas present at fires. The safety hood uses a sponge that is soaked in water, which helps filter out the smoke and cools breathable air as it enters a tube. This device made breathing safer for people exposed

to smoke, gases, and other toxins. His safety hoods were successfully adopted in the Northern United States, but he faced resistance and skepticism in the South, most likely due to his race. However, Morgan was able to demonstrate his invention on July 24, 1916, when a tunnel in Lake Erie collapsed because of a natural gas explosion. Morgan and his brother, Frank, rushed to the scene with several safety hoods. Many of the rescuers were doubtful that Morgan's device would work; however, he proved them wrong. He, his brother, and several volunteer rescuers put on hoods and went into the tunnel. They successfully rescued two men. Because of this incident, the South was more receptive to his invention. Unfortunately, Cleveland officials ignored Morgan's act of heroism and credited other rescuers for their bravery.

In 1917, a group of Cleveland citizens awarded Morgan with a gold medal, thanking him for saving those men in the Lake Erie explosion. Morgan's safety hood became widely used by firefighters. Morgan sold his safety hood to the U.S. Navy, and eventually, the army used it to develop gas masks that were used in World War I. Soon, Morgan's inventions started to gain popularity in North America and England, and demand for them skyrocketed. Morgan later died on July 27, 1963, at age 86.

Motorcycle (Pre–World War II)

The motorcycle originated from the safety bicycle, which has front and rear wheels of the same size and utilizes a pedal crank around the rear wheel. The general concept of the motorcycle was conceived

simultaneously across Europe by various engineers and inventors. The original motorcycle was steam powered and referred to as the “velocipede.” The production of the motorcycle was greatly impacted by World War I's need for effective frontline communication. This helped to launch the Harley-Davidson Motor Company, founded by William Harley and Arthur Davidson, as one of the world's most successful motorcycle companies.

One of the first motorcycles created in the 1860s and originally named the velocipede was created by Pierre Michaux in Paris. This design reached the United States in 1863 via an employee of Michaux. Next came the Roper steam velocipede, built by Sylvester Roper in Boston, Massachusetts. There is debate whether Michaux's or Roper's velocipedes are truly the world's first motorcycles. The first petroleum-fueled, internal combustion motorcycle was the Daimler Reitwagen, designed by German inventors in 1885. It was unlike other bicycles at the time and did not use the principles of bicycle or motorcycle dynamics. The Butler Petrol Cycle, built by the Merryweather Fire Engine Company, was created in 1888 by Edward Butler. It was a three-wheeled gas-powered vehicle and contained a flat, twin four-stroke engine that used water cooling and rotary valves. In 1894, the Hildebrand & Wolfmüller was created, and it was the world's first production motorcycle. Its patent protected a two-cylinder four-stroke engine with a bore and stroke of 90 by 117 millimeters. It could propel a weight of 50 kilograms and had a maximum speed of 45 kilometers an hour. The engine was located on the floor of the frame between its wheels and used hot tube ignition as well as a ventilated tube heater.

In 1898, Triumph, a British motorcycle manufacturing company, shifted its focus from automobiles to motorcycles. It produced its first motorcycle in 1902 fitted with a Belgian-built engine: the model H. Its rear wheel was driven by a belt, and it used an air-cooled, four-stroke, single-cylinder engine. The model H is commonly regarded as the first “modern motorcycle.” The Indian Motorcycle Manufacturing Company, founded by two bicycle racers, created the diamond-framed Indian Single design in 1901. It made 20,000 bikes a year until 1913. Before the war effort, the race to produce motorcycles was inspired by a new

This 1914 photo of the Butte Motorcycle Club demonstrates the popularity of the motorized bicycle, or motorcycle in the early 20th century. (Library of Congress)

machine-based sport that replace the “obsolete” manually pedaled bicycle. Harley-Davidson started to produce its motorcycles in 1903.

In 1917, the United States government purchased over 20,000 motorcycles from Harley Davidson and Triumph for use in World War I. The motorcycles provided effective communications with frontline troops, replacing horses with dispatch riders on motorcycles who carried messages, did reconnaissance, and acted as military police. These first motorcycles included the Triumph Model H.

William Harley was an American engineer and businessman as well as the cofounder of Harley-Davidson Motor Company. Harley was born in Milwaukee, Wisconsin, in 1880 to immigrant parents. At the age of 15, he worked in the Meiselbach bicycle factory, where he drafted plans for an engine to be mounted on a bicycle. Harley received a degree in mechanical engineering from the University of Wisconsin-Madison in 1907. He served as chief engineer and treasurer at Harley-Davidson until his death in 1943.

Arthur Davidson was an American businessman and was one of the original founders of Harley-Davidson. Davidson was born in Milwaukee, Wisconsin,

and was of Scottish descent. In 1903, he went into business with his childhood friend William Harley. Together they built motorcycles in his family’s shed. During World Wars I and II, Harley-Davidson diverted motorcycle production to help outfit soldiers for the war efforts. This was rewarded with troops trained and willing to buy their product, as well as the U.S. government purchasing a surplus exclusively of Harley-Davidson brand motorcycles.

Today the motorcycle is a common means of transportation. Its fuel economy is far superior to that of automobiles, but it sacrifices the safety of an enclosed vehicle. The use of motorcycles today also varies from bikes built for sport as well as bikes built for leisure, like “cruisers.”

National Advisory Committee for Aeronautics (NACA)

The National Advisory Committee for Aeronautics (NACA) is an agency of the U.S. federal government for practicing and promoting aeronautic research. The NACA was established in 1915 and was transformed into the National Aeronautics and Space Administration (NASA) in 1958 in response to the Cold War space race.

Two years before the United States entered World War I, the federal government passed legislation to establish an agency that would coordinate war-related science. When the legislation came before Congress in 1913, it failed, but in 1915, with war looming, the proposal was passed by both houses and signed into law by President Woodrow Wilson. Franklin D. Roosevelt, who was at that time assistant secretary of the navy, endorsed the plans for NACA.

The initial budget of \$5,000 per year limited NACA's influence. President Wilson asked airplane innovators Wilbur and Orville Wright to join the organization in the hopes that they could help promote commercial and military aviation. The organization grew quickly. By 1922, NACA employed over 100 people and by 1938, there were over 400 at four facilities: Langley Aeronautical Laboratory in Virginia, Ames Aeronautical Laboratory at Moffett Field in Northern California, Lewis Research Center in Ohio, and Muroc Flight Test Unit at Edwards Air Force Base in Southern California.

NACA did considerable research with wind tunnels, the first of which it built at Langley. Wind tunnel research helped engineers and scientists better understand aerodynamics and was used to test new airplane and wing designs.

During World War II, NACA pioneered aircraft development, including the game-changing P-51 Mustang. Made by American Aviation, the P-51 was a fighter plane with a considerably longer range than previous fighters. This allowed the plane to accompany bombers farther into enemy territory so the bombers were not left unprotected in the face of enemy fighter airplanes.

In the post–World War II era, NACA focused on supersonic research like that for the NACA X-1, an early rocket-powered aircraft that became the Bell X-1. Key to NACA research was the “area rule” that that determines operating speeds for supersonic aircraft.

In 1958, President Dwight D. Eisenhower oversaw the transformation of NACA to NASA on the principle that the nation needed less military technology development and more peaceful, civilian space science.

Noether, Amalie Emmy (1882–1935)

The algebra theorems of world-renowned Jewish mathematician Amalie Emmy Noether have garnered her the nickname “the Mother of Modern Algebra.” She also made notable contributions to theoretical physics, authoring Noether’s theorem. An émigrée from Nazi Germany, Noether worked at Bryn Mawr College in Pennsylvania, where she taught and researched during the height of her career. Albert Einstein said that she was the most important woman in the history of mathematics.

Noether was born in 1882 to Max and Ida Amalia Noether in southeastern Germany. Max studied mathematics at the University of Heidelberg, where he served as a faculty member for a few years before transferring to the University of Erlangen in 1888. Although Noether spent her childhood education following subjects traditionally studied by young girls, she chose to pursue mathematics as an adult.

In 1900, Noether began attending classes at the University of Erlangen. She furthered her education for a semester at the University of Göttingen in 1903, where she met Hermann Minkowski, Otto Blumenthal, Felix Klein, and David Hilbert, all noted mathematicians. After returning to the University of Erlangen, Noether graduated in 1907 and became the second woman in the school’s history to receive a doctorate. Upon graduating, she worked as a professor without monetary compensation before returning to teach in Göttingen in 1915.

Noether continued to work without pay for years, living in poverty. She considered her work as an educator and mathematician to be a civil service in line with her socialist ideals. When she was paid for her work, she only received a small salary, barely enough to support herself. After World War I, Noether faced discrimination under the Third Reich; despite losing her job as a professor, she continued to reach out to her students to discuss mathematics and their future plans. As her leftist views became more apparent to her students, many of whom leaned toward the right and toward Nazi fascism, they began to resist learning from her. The complaints against her led to her eviction from her home.

Under Nazi Germany’s Law for the Restoration of the Professional Civil Service, many instructors, including Noether, had their teaching licenses revoked for

being Jewish or politically left leaning, under the premise that anyone who did not support right-wing fascist politics was disloyal to Germany. It was clear that due to her cultural heritage and political beliefs, which included pacifism, Noether was not welcome in Germany.

In light of the policies under the Third Reich, many universities in the United States offered refuge for German academics. For example, Albert Einstein and Hermann Weyl, both admirers of Noether’s work and personality, worked at Princeton’s Institute for Advanced Study. In 1933, the American all-women’s college Bryn Mawr expressed interest in giving Noether a position as a professor of mathematics. Noether accepted the offer and immigrated to the United States.

It was at Bryn Mawr that Noether found a strong support network in the mathematics community. She worked with Anna Wheeler, an American mathematician and pioneer in functional analysis. Wheeler and Noether shared a common experience in that they both knew how difficult it was for a woman to be accepted as a serious mathematician. By the 1930s, Wheeler had found acceptance as a full professor and head of the math department at Bryn Mawr; she had spent years being rejected for teaching posts in favor of male mathematicians. While at Bryn Mawr under Wheeler’s wing, Noether developed two of the most crucial theorems (Noether’s theorem and Noether’s second theorem) in modern abstract algebra. Her contributions to mathematic research would also serve as a major influence in the field of theoretical physics. During her career, she published over 40 articles on algebraic math, which were marked by her imaginative thinking. Although Noether was invited to lecture at Princeton, where Albert Einstein taught after emigrating from Germany, the all-female Bryn Mawr remained her academic home.

Noether’s health began to decline in 1935, when doctors discovered an ovarian cyst. After her surgery, Noether developed a high fever and died suddenly. Her funeral was held at Bryn Mawr, and many of her colleagues in her field, such as Hermann Weyl and Richard Bauer, attended. Her ashes are interred at the M. Carey Thomas Library.

Olds, Ransom Eli (1864–1950)

Advertising pitches put millions of Americans behind the wheels of cars with model names like Cutlass, Eighty-Eight, Ninety-Eight, and Toronado. But while these model names are memorable, the name of their make is just as unforgettable: Oldsmobile, named after its creator, Ransom Eli Olds.

Born in Ohio, the youngest son of a father who was a blacksmith and a mother who crafted patterns for a living, Ransom Olds and his family eventually moved to Lansing, Michigan, where he started the Olds Motor Vehicle Company in 1897. The 33-year-old carmaker needed a partner, so copper tycoon Samuel Smith entered the business, and it was renamed Olds Motor Works in 1899. Ransom was named vice president and general manager. By 1901, Olds produced 11 prototypes capable of running on steam, electricity, or gasoline. Of the 11, it was decided to enter a sporty little runabout, the Oldsmobile Curved Dash, in that year's New York Automobile Show. The Curved Dash didn't win any awards, but sales of the car more than made up for any disappointment. With a sticker price of about \$650, it was America's first mass-produced compact car. Olds introduced a stationary assembly line, the first of its kind in the automobile industry. The innovation enabled him to increase his factory's output. Nearly 19,000 Curved Dash cars were sold before the model was discontinued in 1905.

The Curved Dash wasn't all that was being discontinued by Olds Motor Works. The company's namesake was also heading for the exit. Ransom Olds's partnership with the Smith family had become contentious, and tensions escalated when Samuel Smith's son Fred joined the company. Olds and the younger Smith clashed frequently, and in 1904, Olds was dismissed as vice president and general manager. He left the company that same year. General Motors

purchased Olds Motor Works in 1908 and discontinued the Oldsmobile line in 2004.

Olds may have been finished with the Olds Motor Works, but not with cars. He resurfaced as the head of the R. E. Olds Motor Car Company until the threat of a lawsuit from his former partners forced him to change the name. It was then called the REO Motor Car Company, using the initials of Olds's name as an acronym. This simple move kept Ransom Olds out of court and in the car and truck business as REO's president and chairman until 1925. Olds's new company manufactured the REO Speed Wagon, ancestor to the modern pickup truck, from 1919 through the 1950s. A popular 20th-century rock 'n' roll band named itself after the vehicle.

Olds was also an early automobile racing enthusiast. He competed in Florida races in the 1890s and 1910s, in the process innovating racing automobile design. In 1946, Ransom Olds was inducted into the Automotive Hall of Fame. Olds died in Lansing, Michigan, in 1950.

Panama Canal

The Panama Canal, a man-made waterway that connects the Atlantic and Pacific Oceans through the Isthmus of Panama, has a long history. Spain, France, and other countries saw the benefits of a canal there but were unable to make it a reality. Although the United States had to overcome many obstacles, it was eventually able to secure the rights to build the canal, an engineering marvel. Since 2000, when the canal was returned to Panamanian control, it faced problems and world competition.

After Christopher Columbus (1451–1506) completed his first voyage across the Atlantic Ocean and landed in America in 1492, Spain began a massive exploration project of the New World. Columbus himself made several other voyages to the Americas, but he

failed to find a water passage through the two American continents. In 1513, Vasco Núñez de Balboa (1475–1519) was the first European explorer to cross the Isthmus of Panama and see the Pacific Ocean. Seven years later, Ferdinand Magellan (1480–1521) found an ocean passage from the Atlantic to the Pacific Ocean through the lower tip of South America, which came to be known as the Strait of Magellan. In fact, Magellan named the ocean *Mar Pacifico* (peaceful ocean), as his ship survived the tumultuous strait waters and entered the calm waters of the earth's largest ocean in 1520.

The Spanish king Charles V (1500–1558) was the first leader to come up with the idea of constructing a canal across the Isthmus of Panama. Charles V realized that the conquest of Peru, Ecuador, and Asia would be greatly facilitated by a water route through the American continents. In 1534, the king ordered a survey for a Panamanian canal project, but he was forced to abandon the project due to war in Europe. Three hundred years later, the revolutionary Simón Bolívar (1783–1830) hired a British engineer to conduct a study of the Panamanian landscape to determine whether a canal across the isthmus was possible. The engineer produced a positive report, but Bolívar died the next year.

The 13,000-mile (20,900 km) journey that U.S. merchant ships were forced to take from New York to the lower tip of South America and then to San Francisco took months to complete. However, the ability to cut through Panama would reduce the trip to 5,200 miles (8,370 km) and shorten the time by more than half. The tremendous savings in fuel costs and time would greatly benefit American industry. In the mid-1830s, President Andrew Jackson (1767–1845) sent an American negotiator to Bogotá, the capital of Colombia, to try and secure the rights to build a U.S. road across Panama (then a province of Colombia). The plan was to use horse-drawn carriages on the U.S. road to transport merchandise to ships docked at Atlantic and Pacific Ocean ports. Negotiations were going well until a similar Dutch deal in Nicaragua failed. When Jackson heard the news of the failure, he lost interest in the road project.

In the late 1840s, British and American ambassadors negotiated the Clayton-Bulwer Treaty (1850), a partnership between the two nations to build infrastructure in Panama to facilitate transport through the isthmus. The 40-year British-American partnership in Panama

produced railroads but no canal. However, Colombian leaders still longed for a canal through Panama, which they believed would be a big money-making enterprise.

In 1880, the Frenchman Ferdinand de Lesseps (1805–1894), who had gained fame as the builder of the Suez Canal in Egypt, secured a concession from the Colombian government to build a canal in Panama. However, the French venture (1881–1887) failed, because de Lesseps made at least three major mistakes. In his planning, he had failed to factor in the climate of the region, which is much different from the dry Egyptian climate. In Panama, the humid and rainy weather caused mudslides that buried months of excavation. Also, as he had done in Egypt, he insisted on digging a sea-level canal from ocean to ocean. Due to many miles of rocky terrain, however, the task was technologically impossible to accomplish, even by equipment invented more than a century later. Last, he failed to address the problem of disease. Yellow fever, malaria, and other tropical diseases claimed the lives of about 20,000 of his workers.

Having dug less than a third of the way through Panama and spent almost \$300 million, the French enterprise went bankrupt in 1887. Investors in the French company wanted to recover some of their losses. Consequently, in 1889, the French government appointed a liquidation firm, which placed the French company up for sale at a price of \$109 million.

By then, much of the work the company had accomplished had been buried by mudslides. Most of the equipment was worn and rusty. The only real thing of value that the French company held was the concession for the right to build the canal granted by Colombia. However, it was set to expire in a few years, so France urgently needed to sell it, and the United States seemed the most likely buyer. U.S. leaders were, in fact, still interested in building a canal through Central America.

The Spanish American War (1898) between the United States and Spain in the Caribbean had left little doubt about the military strategic importance of a Central American canal. President William McKinley (1843–1901) appointed a Canal Commission to investigate the entire region and report its findings. In 1901, the report stated that a canal through Nicaragua would be the cheapest option. McKinley embraced the recommendation, and the House of Representatives passed a bill to dig in Nicaragua. Before the U.S.

Senate could cast a deciding vote, the French company lowered its price to \$40 million. The Canal Commission switched its recommendation of the canal location to Panama. After McKinley's assassination in 1901, President Theodore Roosevelt (1858–1919) supported the Panama Canal initiative.

In 1901, the first issue that Roosevelt had to address was to negotiate a breakup of the British-American partnership in Panama, which had been established by the Clayton-Bulwer Treaty half a century before. Roosevelt sent Secretary of State John Hay (1838–1905) to secure a new agreement with the British. Hay fulfilled the task that same year. Next, Roosevelt ordered Hay to negotiate terms with Colombia. According to the treaty that Hay and Colombian representatives signed in 1903, Colombia granted the United States the right to build a canal zone six miles wide through Panama. In return, the United States agreed to pay Colombia \$10 million and then annual lease payments of \$250,000 for nine years after the initial payment. The treaty also stated that the lease would be renewable in perpetuity.

The U.S. Senate approved the treaty that same year. However, influential Colombian leaders rejected the terms. After they expressed their disapproval of the treaty, the Colombian congress unanimously rejected it. Roosevelt was furious. Late that year, Panamanians launched a one-day rebellion against Colombia. The rebels formed a government and ratified a constitution. The presence of the USS *Nashville* discouraged a Colombian military response. With one recorded death, the Republic of Panama was established, and the United States immediately extended diplomatic recognition of the new nation.

The Hay-Bunau-Varilla Treaty signed by Panama and the United States contained almost identical terms to the treaty that had previously been negotiated with Colombia. Most important to the United States, the treaty gave it the right to build, run, maintain, and protect a canal through Panama. The swiftness with which the Hay-Bunau-Varilla Treaty was negotiated had a lot to do with Roosevelt's promise that American canal interests in Panama obligated American support for Panama's continued independence. Roosevelt boasted that he had taken the canal zone while Congress continued to debate over it until 1904. Under the circumstances, Congress had little choice but to secure the last remaining rights to the canal by paying the French

company (New Panama Canal Company) its asking price of \$40 million.

Roosevelt became the first president to leave the continental United States while in office. During his visit to the canal zone, he oversaw the work, operated a crane, and encouraged the workers to make the "dust fly." Roosevelt was determined to succeed where the French had failed. He was convinced that success with the canal would prove American technological superiority to the world. He concurrently built up the U.S. Navy and showed it off by sending it on a world tour. Years later, while reflecting on his presidential career, he ranked his role in the Panama Canal as one of his greatest achievements.

However, before the canal could be built, Americans would need to address the same problems that had plagued the French venture 20 years earlier: mudslides, determining the best construction plan, and diseases. By providing viable answers to these problems, the crews created an engineering marvel. To minimize the possibility of mudslides, American engineers ordered crews to cut the canal using wider angles than the French had done, and the new strategy required American crews to excavate four times as much earth. During the entire project, approximately 96 million cubic yards of dirt were excavated, which was enough to pave a road from Earth to the moon. The wider excavation also resulted in a wider canal than had been originally planned.

The second, and closely related, issue was to determine the best construction plan. The French had attempted a sea-level design that had proven disastrous. In contrast, American engineers developed a design with locked chambers that would raise and lower ships as they traveled through the Panamanian landscape. On the Atlantic Ocean side, three locks raised ships 240 feet to the level of a lake. On the Pacific Ocean side, two locks lowered the ships to sea level again. Each of the five locked chambers contained four walls that were 1,200 feet long. Each one of those walls was built using more cement than the then-tallest building in the world. To raise and lower ships, water entered and exited the locked chambers through 15-foot-wide holes. Giant electrical generators powered the gates of each lock, and a railroad-like locomotive towed ships through the locks.

Yet none of these great accomplishments would have been possible if the problem of disease had not

been dealt with. Dr. William C. Gorgas (1854–1920), a military doctor who had been successful in conquering yellow fever in Cuba was sent to Panama in 1906. Gorgas believed that the most effective way to eliminate yellow fever and malaria was by preventing mosquitoes from hatching. In a rainy environment with innumerable pockets of water, his task was formidable. With only seven paid helpers and many volunteers, his team swept through the area emptying all containers of rainwater, spraying a mixture of oil and insecticide, sealing rooms with nets, and isolating infected people. Within a few months, Gorgas was successful in greatly reducing the threat of tropical disease in the canal zone. The canal was completed in 1914, 10 years after construction had begun.

For many years, the canal benefited world trade tremendously by slashing travel times and costs. For example, freighters from East Asia had entered the Gulf of Mexico in 41 days before the use of the canal. In contrast, the same ships reached their destination in 25 days by crossing through the canal. In the 1970s, President Jimmy Carter signed a treaty to return the canal to Panama in 2000. Since that time, the canal

faced the danger of becoming obsolete, as many cargo ships were built too large to fit through the canal. In 2007, Panamanian leaders began a \$5.25 billion expansion project, which added another, deeper lane with larger locks for larger ships.

In 2015, Egyptian leaders announced the expansion of the Suez Canal to cut down on wait times, and a Chinese entrepreneur announced plans to build a canal through Nicaragua.

Primary Document: Excerpt from President Theodore Roosevelt's Message to Congress After Returning from the Canal Zone in Panama (1906)

In December 1906, President Theodore Roosevelt addressed Congress to inform it of the progress being made at the Canal Zone in Panama. Roosevelt had good reason to know—he had visited the Panamanian Isthmus in November. As a result of his investigation, he announced that he would restructure the Isthmian Canal Commission to make the project more efficient. The following is an excerpt of Roosevelt's address to Congress.

December 17, 1906

To the Senate and House of Representatives:

I came to the conclusion that, speaking generally, there was no warrant for complaint about the food. Doubtless it grows monotonous after awhile. Any man accustomed to handling large masses of men knows that some of them, even though otherwise very good men, are sure to grumble about something, and usually about their food. Schoolboys,

college boys, and boarders in boarding houses make similar complaints; so do soldiers and sailors. On this very trip, on one of the warships, a seaman came to complain to the second watch officer about the quality of the cocoa at the seaman's mess, saying that it was not sweet enough; it was pointed out to him that there was sugar on the table and he could always put it in, to which he responded that that was the cook's business and not his. I think that the complaint as to the food on the Isthmus has but little more foundation than that of the sailor in question. Moreover, I was given to understand that one real cause of complaint was that at the government hotels no liquor is served, and some of the drinking men, therefore, refused to go to them. The number of men using the government hotels is steadily increasing.

Of the nineteen or twenty thousand day laborers employed on the canal, a few hundred are Spaniards. These do excellent work. Their foreman told me that

they did twice as well as the West India laborers. They keep healthy and no difficulty is experienced with them in any way. Some Italian laborers are also employed in connection with the drilling. As might be expected, with labor as high priced as at present in the United States, it has not so far proved practicable to get any ordinary laborers from the United States. The American wage-workers on the Isthmus are the highly-paid skilled mechanics of the types mentioned previously. A steady effort is being made to secure Italians, and especially to procure more Spaniards, because of the very satisfactory results that have come from their employment; and their numbers will be increased as far as possible. It has not proved possible, however, to get them in anything like the numbers needed for the work, and from present appearances we shall in the main have to rely, for the ordinary unskilled work, partly upon colored laborers from the West Indies, partly upon Chinese labor. It certainly ought to be unnecessary to point out that the American workingman in the United States has no concern whatever in the question as to whether the rough work on the Isthmus, which is performed by aliens in any event, is done by aliens from one country with a black skin or by aliens from another country with a yellow skin. Our business is to dig the canal as efficiently and as quickly as possible; provided always that nothing is done that is inhumane to any laborers, and nothing that interferes with the wages of or lowers the standard of living of our own workmen. Having in view this principle, I have arranged to try several thousand Chinese laborers. This is desirable both because we must try to find out what laborers are most efficient, and, furthermore, because we should not leave ourselves at the mercy of any one type of foreign labor. At present the great bulk of the unskilled labor on the Isthmus is done by West India negroes, chiefly from Jamaica, Barbados, and the other English possessions. One of the governors of the lands in question has shown an unfriendly disposition to our work, and has thrown obstacles in the way of our getting the labor needed; and it is highly undesirable to give any outsiders the impression, however ill-founded, that they are indispensable and can dictate terms to us.

The West India laborers are fairly, but only fairly, satisfactory. Some of the men do very well indeed; the better class, who are to be found as foremen, as

skilled mechanics, as policemen, are good men; and many of the ordinary day laborers are also good. But thousands of those who are brought over under contract (at our expense) go off into the jungle to live, or loaf around Colon, or work so badly after the first three or four days as to cause a serious diminution of the amount of labor performed on Friday and Saturday of each week. I questioned many of these Jamaica laborers as to the conditions of their work and what, if any, changes they wished. I received many complaints from them, but as regards most of these complaints they themselves contradicted one another. In all cases where the complaint was as to their treatment by any individual it proved, on examination, that this individual was himself a West India man of color, either a policeman, a storekeeper, or an assistant storekeeper. Doubtless there must be many complaints against Americans; but those to whom I spoke did not happen to make any such complaint to me. There was no complaint of the housing; I saw but one set of quarters for colored laborers which I thought poor, and this was in an old French house. The barracks for unmarried men are roomy, well ventilated, and clean, with canvas bunks for each man, and a kind of false attic at the top, where the trunks and other belongings of the different men are kept. The clothes are hung on clotheslines, nothing being allowed to be kept on the floor. In each of these big rooms there were tables and lamps, and usually a few books or papers, and in almost every room there was a Bible; the books being the property of the laborers themselves. The cleanliness of the quarters is secured by daily inspection. The quarters for the married negro laborers were good. They were neatly kept, and in almost every case the men living in them, whose wives or daughters did the cooking for them, were far better satisfied and of a higher grade than the ordinary bachelor negroes. Not only were the quarters in which these negro laborers were living much superior to those in which I am informed they live at home, but they were much superior to the huts to be seen in the jungles of Panama itself, beside the railroad tracks, in which the lower class of native Panamans live, as well as the negro workmen when they leave the employ of the canal and go into the jungles. A single glance at the two sets of buildings is enough to show the great superiority in point of comfort, cleanliness, and healthfulness of the

Government houses as compared with the native houses.

The negroes generally do their own cooking, the bachelors cooking in sheds provided by the Government and using their own pots. In the different camps there was a wide variation in the character of these cooking sheds. In some, where the camps were completed, the kitchen or cooking sheds, as well as the bathrooms and water-closets, were all in excellent trim, while there were board sidewalks leading from building to building. In other camps the kitchens or cook sheds had not been floored, and the sidewalks had not been put down, while in one camp the bath houses were not yet up. In each case, however, every effort was being made to hurry on the construction, and I do not believe that the delays had been greater than were inevitable in such work. The laborers are accustomed to do their own cooking; but there was much complaint, especially among the bachelors, as to the quantity, and some as to the quality, of the food they got from the commissary department, especially as regards yams. On the other hand, the married men and their wives, and the more advanced among the bachelors, almost invariably expressed themselves as entirely satisfied with their treatment at the commissary stores; except that they stated that they generally could not get yams there, and had to purchase them outside. The chief complaint was that the prices were too high. It is unavoidable that the prices should be higher than in their own homes; and after careful investigation I came to the conclusion that the chief trouble lay in the fact that the yams, plantains, and the like are rather perishable food, and are very bulky compared to the amount of nourishment they contain, so that it is costly to import them in large quantities and difficult to keep them. Nevertheless, I felt that an effort should be made to secure them a more ample supply of their favorite food, and so directed; and I believe that ultimately the Government must itself feed them. I am having this matter looked into.

The superintendent having immediate charge of one gang of men at the Colon reservoir stated that he endeavored to get them to substitute beans and other nourishing food for the stringy, watery yams, because the men keep their strength and health better on the more nourishing food. Inasmuch, however, as they are accustomed to yams it is difficult to get them to

eat the more strengthening food, and some time elapses before they grow accustomed to it. At this reservoir there has been a curious experience. It is off in the jungle by itself at the end of a couple of miles of a little toy railroad. In order to get the laborers there, they were given free food (and of course free lodgings); and yet it proved difficult to keep them, because they wished to be where they could reach the dramshop and places of amusement.

I was struck by the superior comfort and respectability of the lives of the married men. It would, in my opinion, be a most admirable thing if a much larger number of the men had their wives, for with their advent all complaints about the food and cooking are almost sure to cease.

I had an interview with Mr. Mallet, the British consul, to find out if there was any just cause for complaint as to the treatment of the West India negroes. He informed me most emphatically that there was not, and authorized me to give his statement publicity. He said that not only was the condition of the laborers far better than had been the case under the old French Company, but that year by year the condition was improving under our own regime. He stated that complaints were continually brought to him, and that he always investigated them; and that for the last six months he had failed to find a single complaint of a serious nature that contained any justification whatever.

One of the greatest needs at present is to provide amusements both for the white men and the black. The Young Men's Christian Association is trying to do good work and should be in every way encouraged. But the Government should do the main work. I have specifically called the attention of the Commission to this matter, and something has been accomplished already. Anything done for the welfare of the men adds to their efficiency and money devoted to that purpose is, therefore, properly to be considered as spent in building the canal. It is imperatively necessary to provide ample recreation and amusement if the men are to be kept well and healthy. I call the special attention of Congress to this need.

This gathering, distributing, and caring for the great force of laborers is one of the giant features of the work. That friction will from time to time occur in connection therewith is inevitable. The astonishing

thing is that the work has been performed so well and that the machinery runs so smoothly. From my own experience I am able to say that more care had been exercised in housing, feeding, and generally paying heed to the needs of the skilled mechanics and ordinary laborers in the work on this canal than is the case in the construction of new railroads or in any other similar private or public work in the United States proper; and it is the testimony of all people competent to speak that on no other similar work anywhere in the Tropics—indeed, as far as I know, anywhere else—has there been such forethought and such success achieved in providing for the needs of the men who do the work.

I have now dealt with the hygienic conditions which make it possible to employ a great force of laborers, and with the task of gathering, housing, and feeding these laborers. There remains to consider the actual work which has to be done; the work because of which these laborers are gathered together—the work of constructing the canal. This is under the direct control of the Chief Engineer, Mr. Stevens, who has already shown admirable results, and whom we can safely trust to achieve similar results in the future.

Our people found on the Isthmus a certain amount of old French material and equipment which could be used. Some of it, in addition, could be sold as scrap iron. Some could be used for furnishing the foundation for filling in. For much no possible use could be devised that would not cost more than it would bring in.

The work is now going on with a vigor and efficiency pleasant to witness. The three big problems of the canal are the La Boca dams, the Gatun dam, and the Culebra cut. The Culebra cut must be made, anyhow; but of course changes as to the dams, or at least as to the locks adjacent to the dams, may still occur. The La Boca dams offer no particular problem, the bottom material being so good that there is a practical certainty, not merely as to what can be achieved, but as to the time of achievement. The Gatun dam offers the most serious problem which we have to solve; and yet the ablest men on the Isthmus believe that this problem is certain of solution along the lines proposed; although, of course, it necessitates great toil, energy, and intelligence, and although equally,

of course, there will be some little risk in connection with the work. The risk arises from the fact that some of the material near the bottom is not so good as could be desired. If the huge earth dam now contemplated is thrown across from one foothill to the other we will have what is practically a low, broad, mountain ridge behind which will rise the inland lake. This artificial mountain will probably show less seepage, that is, will have greater restraining capacity than the average natural mountain range. The exact locality of the locks at this dam—as at the other dams—is now being determined. In April next Secretary Taft, with three of the ablest engineers of the country—Messrs. Noble, Stearns, and Ripley—will visit the Isthmus, and the three engineers will make the final and conclusive examinations as to the exact site for each lock. Meanwhile the work is going ahead without a break.

The Culebra cut does not offer such great risks: that is, the damage liable to occur from occasional land slips will not represent what may be called major disasters. The work will merely call for intelligence, perseverance, and executive capacity. It is, however, the work upon which most labor will have to be spent. The dams will be composed of the earth taken out of the cut and very possibly the building of the locks and dams will take even longer than the cutting in Culebra itself.

The main work is now being done in the Culebra cut. It was striking and impressive to see the huge steam shovels in full play, the dumping trains carrying away the rock and earth they dislodged. The implements of French excavating machinery, which often stand a little way from the line of work, though of excellent construction, look like the veriest toys when compared with these new steam shovels, just as the French dumping cars seem like toy cars when compared with the long trains of huge cars, dumped by steam plows, which are now in use. This represents the enormous advance that has been made in machinery during the past quarter of a century. No doubt a quarter of a century hence this new machinery, of which we are now so proud, will similarly seem out of date, but it is certainly serving its purpose well now. The old French cars had to be entirely discarded. We still have in use a few of the more modern, but not most modern, cars, which hold but

twelve yards of earth. They can be employed on certain lines with sharp curves. But the recent cars hold from twenty-five to thirty yards apiece, and instead of the old clumsy methods of unloading them, a steam plow is drawn from end to end of the whole vestibuled train, thus immensely economizing labor. In the rainy season the steam shovels can do but little in dirt, but they work steadily in rock and in the

harder ground. There were some twenty-five at work during the time I was on the Isthmus, and their tremendous power and efficiency were most impressive.

Pennington, Mary Engle (1872–1952)

Bacteriological chemist and refrigeration engineer Mary Engle Pennington is most famous for advancements in refrigeration technology. She was also the first female lab chief at the U.S. Food and Drug Administration. The advancements she made were spurred by her involvement in the effort during World War I to improve refrigeration of perishable food sent to overseas troops.

Pennington was born in Nashville, Tennessee, on October 8, 1872. Her family moved to Philadelphia; Pennington attended the Towne Scientific School there, where she completed the required courses for a degree in chemistry and minors in botany and zoology in 1892. The university did not grant degrees to women, so she received a certificate of achievement for her studies. In 1895, she earned her PhD from the University of Pennsylvania, one of the few universities at the time to grant degrees to women.

Upon graduation, Pennington was unable to find employment. She formed her own laboratory group in Philadelphia before finding a job at the Philadelphia Bureau of Health, where, as a bacteriologist, she worked on improving sanitation standards for the handling of dairy products. In 1905, she went to work for the U.S. Department of Agriculture (USDA) as a bacteriological chemist. There, she set standards for the safe processing of chickens raised for human consumption. Two years later, she became the chief of the USDA's new Food Research Laboratory. Her then boss, Harvey Wiley, had put her name up for the job, disguising the fact that she was a woman by using her initials on the job application. Once the ruse was discovered, Wiley defended Pennington's hiring, arguing

that no federal law prevented women's employment in the USDA.

In the 1910s, she headed a team of researchers to improve the functioning of refrigerated railroad cars, with the aim of making food safer for World War I soldiers. The advancements and research conducted at the Food Research Laboratory during the war led to interest in the entire process of storing and transporting perishable food. In 1923, Pennington founded the Household Refrigeration Bureau to bring awareness to the public on safe practices in domestic refrigeration. In addition, she had support from the National Association of Ice Industries to produce and distribute pamphlets on home food safety.

Ultimately, Pennington's work aided in keeping a low bacterial count in refrigerated foods that were critical to food safety and purity. In efforts to refine and improve food preservation techniques, Pennington suggested the preservation of food through freezing at a time when practices such as smoking and canning dominated the industry.

The American Chemical Society gave Pennington the Garvin-Olin Medal for achievements in chemistry. She is also a 2002 inductee of the Women's National Hall of Fame.

Petroleum Industry (Pre–World War II)

Modern society has become increasingly reliant on oil. The widespread use of cars and plastic has turned what used to be a relatively mundane resource into something vital for the world that we live in today. However, it was during the 19th century that oil became the modern necessity that American society relies upon.

All throughout human history, oil was used in one way or another. Many cultures around the world used it for waterproofing wooden ships. There were also other practical and medicinal uses of oil in some societies, such as records from 1298 of Marco Polo describing it being burned to provide light, or Francisco Ariosto writing about oil from springs being used as a medicine. In 1625, Johan Volck wrote a paper exploring possible uses for the oil found in the Pechelbronn district of Alsace, but he found no financial backers for his proposed experiments. Oil was used in various cultures but not industrialized or extracted on a wide scale until quite late in history, and it was not yet a viable general energy source.

More modern uses of oil appeared in the first half of the 1800s. The large-scale machinery that industrialization brought required frequent lubrication to prevent wear and breakage, and while many oils and lubricants were based on animal products, others made use of petroleum oil from within the earth.

In 1853, kerosene was first distilled by Ignacy Łukasiewicz. Not long after that, more commodities would be developed using oil, and all around the world, oil industries began to spring up in several countries. As the world industrialized, more and more of it developed a craving for oil, and this demand made its extraction a profitable venture; it was thus commercialized. Several prominent developers laid their claims on oil reserves all around the world—notably the Seneca Oil Company of New Haven, Connecticut, and the Virginia Petroleum Company. This pattern occurred across the world, with oil reserves being claimed in Russia under the orders of the czar. Soon, oil was carried to major cities for refinement and processing.

In the 1800s, more oil was discovered, claimed, and drilled for. The United States developed a large

oil industry, and the oil companies consolidated their power, dominated by the trusts—several companies merging to create a monopoly on one particular resource. So, in the United States, oil was placed in the hands of relatively few owners. By the 1900s, with the acquisition of the Pacific Oil company, Standard Oil would control over 90 percent of oil refining within the United States—practically the only source of refined oil in the country. With its domination of what was quickly becoming a vital resource, the industrial giant obtained great political power.

The trust became the target of various smear campaigns at the beginning of the 20th century. Public opinion was beginning to turn against the notion of monopolies, because they had complete control over prices in specific markets. Standard Oil was not immune to antitrust campaigns and eventually, government policy turned against it. In 1911, the U.S. Supreme Court finally broke up the oil trust into smaller companies to encourage competition.

By this point, oil had risen in importance in modern society and become an important strategic resource the world over. With the increasing industrialization of the European nations, Britain had converted its entire navy from coal to oil power by 1905. The beginning of the 20th century brought major discoveries of oil in the Middle East. Companies set themselves up to establish control over Middle Eastern oil. Over the next several years, oil was discovered in various colonies of the world's superpowers. While the United States had its own domestic oil reserves, increased demand continued to drive American foreign policy.

The superpowers clashed in 1914 with the beginning of World War I. Like many other resources, oil became essential in the war effort, especially for fueling aircraft and land vehicles for the military. Even with the United States' late entry into the war, the development of industry and military buildup ensured that even an isolationist United States would continue to increase its demand for oil.

After World War I, the tank and other vehicles would replace many of the military roles that horses had previously played. The modernization of armies meant replacing the horse with the automobile. This

trend spilled over into the civilian sector as the horse was replaced with the car, and older coal- and steam-driven train engines would be steadily replaced with newer, diesel-powered trains.

The demand for oil escalated in the United States after World War I. In 1923, Edward Doheny's Pan American Petroleum and Transport Company tapped large oil reserves in Alaska. New methods were being developed to refine oil in the 1920s, such as the gravity method and the seismic method, allowing for more types of deposits to be extracted.

In this era, several of the oil companies that we are familiar with today began to form, including Standard Oil of Indiana, which became Amoco, and Standard Oil of New York, which became Mobil. In 1932, the discovery of oil in California saw Standard Oil of California, the company that would later become Chevron, grow and prosper.

In 1930, U.S. oil prices collapsed. The discovery of the East Texas oil fields suddenly flooded the market with new supplies of U.S. oil. This required a regulatory commission to be founded to properly regulate oil production in Texas and help to stabilize the market after this economic disaster. These efforts would not be fruitful until 1931, when, despite resistance from the oil producers themselves and several legal battles, regulatory commissions helped to establish some order in this chaotic new discovery.

U.S. oil companies also secured oil rights in South America, Saudi Arabia, Eastern Europe, and other international locations. International ventures frequently merged with U.S. companies, and through this, the United States gained international economic influence. Oil productions increased into the millions of barrels per day for a single company.

In the late 1800s, oil became a valuable resource even before the invention and widespread adoption of oil products as fuel. As the automobile and other vehicles switched from coal to diesel, militaries the world over were some of the first to adopt oil as fuel on a wide scale, skyrocketing demand. This prompted the development of oil extraction, refinement, and technology tools. While before World War II, there might not have been a car in every garage, industrial and commercial tasks were being fueled by oil. What at

one time was seen as a specialty product quickly grew into the necessary resource we know it as today. This era laid the foundations of oil as humanity's primary method of energy generation, and events such as World War I began to introduce the world to the automobile, airplane, and other vehicles that replaced horses.

Pop-Up Toaster

Early toasters browned bread on one side at a time, and they required constant supervision to prevent burning the bread. In 1919, Charles Strite invented the first automatic pop-up toaster for restaurant use. His patent was granted in 1921, and the toaster was produced by the Waters Genter Company.

Strite's "Toastmaster" could brown bread on both sides simultaneously, turn off the heating element, and eject the toast when ready. It contained a series of four levers and buttons. The timing lever wound up the spring motor that operated the timing mechanism. The toast lever lowered the bread into the toaster and turned on the electric current. As the timing lever rose, it approached the top of the toaster until it tripped an automatic shutoff that broke the current and released the toast lever, thus removing the toasted bread from the heat source.

The directions for the toaster cautioned users about the ideal consistency and thickness of the bread slices to be toasted. Sales of the Toastmaster were

This 1921 toastmaster was the first home use pop-up toaster. It could brown bread on both sides simultaneously and eject the toasted bread when the variable timer went off. (Tara Walton/Toronto Star via Getty Images)

greatly increased when the Continental Baking Company began selling presliced Wonder Bread.

Pushpin

The pushpin was an invention by Edwin Moore, an inventor from Newark, New Jersey. In 1899, he filed a patent for a pin with a handle that allowed people to stick papers and others notes to a corkboard.

The intent of the original design of the pin was for the user to stick it into something easily, for whatever it was coated with to be resistant to corrosion, and for it to be cheaply mass-produced.

The patent also included the idea of modification and decoration on the top of the pin for purely aesthetic reasons. The patent gave the example of the top of the pin being replaced with a decorative pig's head made from molded or fabricated celluloid.

After the patent was accepted, Moore began to produce pushpins himself. After a large order from the Eastman Kodak Company, sales of Moore's pins began to be successful. The Moore Push-Pin Company still exists today, operating out of Wyndmoor, Pennsylvania.

Radio

Radio technology utilizes electromagnetic radiation (radio waves) to transmit and receive information. Many scientists contributed to the development of radio. Based on telegraph technology, radio evolved from a primitive, one-to-one short-distance wireless transmission system to a long-distance, digital, satellite-powered network capable of delivering a signal to a wide area.

The radio industry had a tremendous cultural influence on daily life. Even though radio's Golden Age was eclipsed by the advent of television, the radio industry remained relevant. The constant growth of the industry led to government regulation. Ongoing innovations in radio technology have resulted in new applications, discoveries, and opportunities.

The Italian Guglielmo Marconi (1874–1937) has traditionally been regarded as the "Father of Radio"; however, many people contributed to the development of radio technology. In fact, single-wire telegraph technology, invented and patented by Samuel Morse (1791–1872) in 1844, served as the basis for radio technology. In the late 1800s, British scientist James Clerk Maxwell (1831–1879) and German scientist Heinrich Hertz (1857–1894) were

the first to theorize and verify through experimentation the existence of wireless electromagnetic waves.

Based on these developments, in 1894, British scientist Oliver Lodge (1851–1940) developed equipment capable of sending and receiving a weak wireless electromagnetic Morse code signal (of a few dots and dashes) across a maximum distance of 55 meters. Although still in the prototype stage, Lodge's achievement was a great leap forward in the historical development of radio. During the next few years, scientists in Italy, France, Russia, and Brazil successfully duplicated Lodge's feat.

Marconi was the first to send and receive wireless telegraph messages across much wider distances by transmitting from tall masts and bouncing signals off the ionosphere (a layer of the earth's atmosphere) and over the horizon. After receiving a patent for his invention in 1896, Marconi demonstrated it to the world by transmitting across the English Channel (1899) and the Atlantic Ocean (1901). Marconi envisioned radio ideally as a means of one-to-one (private) contact between merchant ships and the armed forces.

Based on Marconi's success in telegraphy (the process for sending and receiving wireless telegraph messages), in 1902, Danish scientist Valdemar Poulsen (1869–1942) introduced telephony (the process for sending and receiving sound) by modulating the electromagnetic signal into a continuous wave. In 1906, Canadian Reginald Fessenden (1866–1932) successfully broadcasted voices and music across the Massachusetts coastline. Several other scientists were responsible for developments in radio equipment (including the diode and dynamic speakers) that made it possible to amplify radio signals and send them to wider audiences, but Fessenden's accomplishment was most responsible for introducing the possibility that radio technology could go beyond Marconi's original limited vision.

Although radio was, in fact, used as Marconi had envisioned, after World War I (1914–1918), it was also more popularly used as a means for mass communication and entertainment. For example, with a focus on passenger safety, in 1910 the

U.S. Congress passed the Wireless Ship Act, which required that all oceangoing passenger ships be equipped with a radio and a radio operator. Also, during World War I, the military used radio technology as a vital communication tool. However, by 1922, the number of privately owned and operated radio stations with an emphasis on consumer culture had increased dramatically in both Britain (150) and the United States (500).

Through experimentation, scientists discovered the limits of the radio spectrum. They found that its lower end is not suited for communication, because the data rate decreases as frequency decreases. On the other hand, at the higher end of the radio spectrum, signals fail to bounce back to earth and are instead absorbed into the atmosphere. Consequently, after government officials were made aware that the radio spectrum was finite real estate, they took steps to regulate it in the face of a booming radio industry. President Calvin Coolidge signed the Radio Act of 1927, which established the Federal Radio Commission (FRC).

In 1934, the FRC was replaced by the Federal Communications Commission (FCC), which took steps to allocate and monitor the use of the radio spectrum for nongovernment entities. In addition, both the FCC and the National Association of Broadcasters issued a code of ethics for radio programming and advertising. The codes (or rules) were intended to ensure that radio broadcasters served the public interest in a fair and trustworthy manner. However, the codes, which forbade indecency, obscenity, and the use of profanity, created an ongoing tension between rule makers and free-speech proponents who viewed the enforcement of the broadcasting rules as censorship. In more recent years, regulators have given satellite, cable, and Internet radio broadcasters much more freedom of expression.

During the 1920s, the radio was one of the most popular household appliances. By 1933, two-thirds of all homes in the United States had radios (twice the number of homes with telephones). The radio transformed daily life, and it brought the family together. After dinner, millions of families gathered around the radio and listened to a variety of programs,

including music, sporting events, soap operas, comedy shows, worship services, weather forecasts, and newscasts on national and world events. In short, the radio connected people to the outside world like never before.

Beginning with President Calvin Coolidge (1872–1933), presidents utilized the radio to address the nation. In fact, during the Great Depression (1929–1939) and World War II (1939–1945), President Franklin Delano Roosevelt (1882–1945) used the radio to deliver his monthly “fireside chats,” which gave millions of Americans hope. Beginning in 1922, radio advertising promoted consumer culture—the sale of a variety of consumer goods, including food, household appliances, soap, and automobiles. Radio music broadcasts also influenced music fads. For example, jazz, as well as country and western music, which had been popular in isolated regions of the nation, exploded on the national stage in the 1920s due to radio airplay. The phenomenon reoccurred with rock ‘n’ roll music and the rise of popular artists like Elvis Presley in the mid-1950s. In fact, the tremendous influence of radio remained unmatched for almost half a century until it was eclipsed by television in the late 1950s.

As had been the case during World War I, during World War II, the military used the radio as an indispensable communication tool. However, the World War II era produced many more innovations in radio technology. Two of the most significant advances included the mobile radio transmitter and receiver (that was operable during land, air, and sea transport) and radar (used to locate enemy submarines so they could be destroyed).

Although the supremacy of radio in daily life was dashed by television, radio remained an important fixture in the world. For example, between 1945 and 1960 (before a significant number of man-made satellites orbited the earth), many television stations used microwave radio technology to enable them to boost their signals so that they could broadcast nationally. One reason that radio fostered a growing audience after the advent of television was that transistor radios were much more portable and cheaper than televisions. As television transitioned from black-and-white

programming to color in an attempt to capture more viewers, radio evolved to include stereo frequency modulation (FM) alongside mono amplitude modulation (AM).

There were 2,300 radio stations in the United States in 1972. By 1976, the number had grown to 3,700—so rapidly that Congress created the National Telecommunications and Information Administration (NTIA) in 1978 to reassess and reallocate frequencies within the spectrum and to reduce the possibility of radio interference between allocated stations.

In the 1980s and 1990s, NTIA regulation of radio grew in importance as the spectrum continued to grow crowded with both private and public radio stations. In the mid-1990s, some European radio stations began offering higher-fidelity sound than FM by broadcasting digital recordings in a digital format. Within a few years, American stations began adopting the digital audio broadcasting (DAB) format. Besides the advantage of better sound quality, digital signals could be compressed, which resulted in more room for stations within the spectrum. Besides profits generated by radio stations, technological advancements in radio technology encouraged the growth of the radio industry.

By 2000, there were more than 12,000 stations in the United States broadcasting with the aid of satellite networks. By 2001, there were 13,000 American stations that reached 95 percent of all consumers every week. Another rising star in the radio industry was Internet radio. By 2000, numerous Internet radio stations offered streaming personalized digital content. Advancements in radio technology led to new uses. Today, cordless telephones and wireless streaming audio and video feeds use low-powered radio transmitters and receivers. In like manner, cellular telephones use wireless radio technology to connect to distant phone lines. Satellite radio providers beam digital radio content down to earth, where subscribers with special receivers decode radio signals.

Some groups became alarmed by the proliferation of devices (such as mobile cellular phones, wireless Internet connections, radars, and radio and television transmitters) that were constantly bombarding the

human body with radio waves. Although the topic remained controversial, some believed that sufficient intensity and/or duration of exposure to electromagnetic radiation could harm humans, resulting in various illnesses including chronic headaches, insomnia, depression, and cancer. While experiments showed that extremely high levels of radio waves could cause tissue damage, most radio wave intensity (emitted from cellular phone base stations and television transmitting stations) were typically thousands of times lower than radio wave intensity emitted by devices close to the body. In addition, scientists were unable to find a direct link between radio waves and any specific illness.

The National Environmental Policy Act of 1969 required the FCC to regulate consumer exposure to radio waves. In 1996, the FCC set the maximum permissible exposure limits for field strength and power density for transmitters operating at frequencies of 300 kHz to 100 GHz. In addition, the FCC set specific absorption rate (SAR) limits for devices operating within close proximity to the body, which manufacturers had to comply with. Various consumer support groups issued guidelines that people could follow to reduce exposure.

Radio technology also offers humanity an opportunity to better understand the universe. In 1932, Karl Jansky (1905–1950) discovered radio noise in the Milky Way galaxy. The discovery led to the establishment of radio astronomy. The radio telescope is an astronomical instrument consisting of a radio receiver and an antenna system that is used to detect radio frequency radiation emitted by extraterrestrial sources. Today, there are hundreds of ground-based radio telescopes all around the world as well as space-based radio telescopes. Radio telescopes inside the solar system have given us a much better understanding of planet orbit patterns and the imaging of asteroids.

Beyond the solar system, the use of radio telescopes has led to the discovery of different kinds of pulsars. In general terms, the use of radio telescopes has given scientists the ability to observe the universe in new ways that would otherwise not be possible. Radio telescopes also offer hope for discoveries that have not yet been made. For example,

since the 1960s, several groups of scientists, including those who created the most well known program, the Search for Extra Terrestrial Intelligence (SETI), pointed radio telescopes into space with the intent of locating extraterrestrial radio signals. However, the scant years of searching for radio waves, which travel at the speed of light, have not yet led to the discovery of alien signals in a vast and expanding universe that is more than 27 billion light-years wide.

Primary Document: “Radio’s Real Uses” by E. E. Free, Science Editor for *The Forum* (1926)

The 1920s saw significant anxiety about the new technology that was the radio. New York governor Al Smith proclaimed the radio useless in national politics because it was only good for facts and no good for making appeals to passion. The science editor for a national magazine, The Forum, thought differently.

Radio broadcasting is spectacular and amusing but virtually useless. It is difficult to make out a convincing case for the value of listening to the material now served out by the American broadcasters. Even if the quality of this material be improved, as it undoubtedly will be, one must still question whether the home amusement thus so easily provided will sufficiently raise the level of public culture to be worth what it costs in time and money and the diversion of human effort. It is quite possible to argue, indeed, that the very ease with which information or what-not reaches one by radio makes it just so much the less valuable. In educational matters, as in commerce, men usually value things by what they cost. Culture painlessly acquired is likely to be lost as painlessly—and as promptly. Is the whole radio excitement to result, then, in nothing but a further debauching [morally corrupting] of the American

mind in the direction of still lazier cravings for sensationalism? I believe not. There are at least two directions, quite different ones, in which radio has already proved its utility and its right to survive. One of these is its practical service as a means of communication. The other is its effect, continually growing more evident, in stimulating the revival of that exceedingly useful and desirable creature, the amateur scientist.

I had not, up to that time, thought of it [radio] as a sort of mental hypodermic [injection]. I had, as a matter of fact, connected it principally with the national defense, and I remember that originally I had some vague notion about the service the radio would render in times of war, in the matter of expediting [sending] messages, detecting spies, etc. Of course I knew that it was a Tremendous Contribution—to what or to whom I was not exactly sure, but I had heard it styled so by ministers in the pulpit, and I was sure that in time it would be included in school histories under the chapter entitled Benefits of Inventions and Discoveries, which explained how much the cotton gin, the locomotive, the telephone, and the motion picture had done for civilization. By actual contact, however, both as a listener and as a broadcaster, I learned that the radio was associated

with that other form of service which is a sort of national rallying cry in America, "Service," with a capital S, that intangible something, which the merchant professes to confer upon you in addition to the goods for which you pay; Its programs were free. You could tune in anywhere without even giving a tithe to the government. As one station sang nightly: Just set your dial And stay a while With W-X-Y-Z. There it is, up in the air, absolutely free, waiting for you to pull it down with the aid of electricity. Opera and symphonic music, jazz, twenty minutes of good reading, how to cook by Auntie Jane, tales for the kiddies and prayers set to music, even "Now I lay me

down to sleep"; sermons and exhortations not to drink, gamble, and blaspheme, with music by the white-robed choir; advice on how to spread your income by investment brokers; advice on how to make your shoes last longer by shoe salesmen; talks by the mayor on civic duty, on "Your Boy" by the master of the Boy Scouts; on the right sort of boys by the head of the Y.M.C.A., and the right sort of girls by the head of the Y.W.C.A.; barn dances, recitals of music schools, whole acts of plays, speeches, speeches, speeches.

Rocky Mountain Laboratories

The Rocky Mountain Laboratories (RML) was established in 1928. The facility is a biosafety 4 laboratory. Researchers at the RML pioneered research into Rocky Mountain spotted fever.

In the late 19th and early 20th centuries, the Western United States were plagued with a disease called "black measles." Now known as Rocky Mountain spotted fever, the disease often proved fatal. Montana's newly formed State Board of Health began investigating the disease in 1901. Researchers set up camp in the Bitterroot Valley of western Montana, working from log cabins and canvas tents. In 1906, Howard Ricketts proved that the disease was communicated by tick bite, contrary to local legend, which held that one contracted the disease from drinking snowmelt. In 1910, Ricketts left the facility to study typhus in Mexico City. He contracted typhus and died. In honor of his contributions the organism that causes Rocky Mountain spotted fever is named *Rickettsia rickettsii*.

In 1910, Clarence Birdseye joined the research facility as a tick collector as part of his work for the U.S. Biological Survey. Montana instituted a tick eradication program that made some headway against the disease. In 1927, the Montana state legislature approved funding for Rocky Mountain Labs in Hamilton to study ticks and Rocky Mountain spotted fever. Hamilton residents opposed the new lab, arguing that ticks

would escape the facility and infect locals. Thus, a moat was built around the facility, based on the fact that ticks cannot swim. The new facility employed 4 professional researchers and 22 support staff personnel.

In 1937, the RML became part of the National Institute of Health. The laboratory worked on vaccines for typhus and yellow fever during World War II, both diseases that plagued soldiers worldwide.

In the 21st century, the RML continues to lead disease research. The facility functions as a maximum containment laboratory working on chronic wasting disease, Q fever, chlamydia, Lyme disease, tularemia, influenza, and much more.

Safety Razor

Before the 1900s, men all over the world struggled to find a safe and easy way to shave off facial hair. King Camp Gillette patented an improved safety razor in 1904 that revolutionized body hair removal.

Before the invention of the safety razor, men used a variety of methods to remove facial hair. As early as 30,000 BC, they used clamshells for this. By 3000 BC, ancient Egyptians used copper razors, and in 1500 BC, bronze razors appeared in Scandinavia.

In the 1600s, steel-edged straight razors, sometimes called “cutthroat razors,” appeared in England. In 1770, a French barber named Jean-Jacques Perret invented a single-blade razor with a folding wooden handle that functioned as a guard. This became the razor of choice for men until the 20th century.

Gillette did not invent the safety razor. German American brothers Frederick and Otto Kampfe patented a forged-blade safety razor in 1875. But forged blades dulled after use and were expensive.

King Gillette determined to change men’s shaving experience by designing a safe and disposable razor. Gillette faced a few problems. First, he couldn’t find a way to construct razor blades thin enough. Second, because he couldn’t develop the blades for his disposable razor, he couldn’t find any investors to support his product.

Machinist William Emery Nickerson, who was also Gillette’s partner, solved the problem by designing a machine that could manufacture thin blades. He also changed the razor’s handle design. From that innovation, the Gillette brand flourished. Although their endeavors were a success, they still had a bit of trouble convincing the rest of the world that disposable razor blades were as effective as the traditional straight razor blades.

Gillette marketed the razors using what is now called the “razor and blade business model.” They sold their razors at a steeply discounted price and then made money from selling consumers the blades that went into them. This model, where an item is sold cheaply and a complementary item is sold for higher prices, became an industry standard for a number of consumer products, including printers and ink cartridges, video game consoles and games, and more.

The safety razor blade continues to evolve. What started out as a metal razor with one blade is now available in an assortment of razors with multiple blades. Many razors have plastic handles and are

disposable in their entirety (rather than just the blade being disposable).

Scotch Tape

“Scotch tape” is both a brand name and common use name for transparent tape. Richard Drew invented Scotch tape while working for 3M Company in Minnesota in 1925.

Before inventing Scotch tape, Drew invented masking tape. Two-tone paint jobs were popular automobile paint schemes in the 1920s, and Drew learned that it was difficult for auto painters to create a clean border between two paint colors. In 1922, he developed a two-inch-wide, paper-backed, pressure-sensitive strip that had adhesive along its edges but not in the center. The tape did not stick well, causing an auto painter to suggest that the “Scotch bosses” at 3M use more adhesive—“Scotch” being a slang word for “cheap.”

In 1925, Drew invented the first transparent tape, then called Sellotape.

Drew’s tape used a cellophane, rather than paper, backing. Tape made by 3M and many other companies sold well during the Great Depression because it was an affordable way for people to repair everyday objects that they could not afford to replace. Today, transparent tape is commonly used worldwide in households, classrooms, and places of business.

Subway System of New York City

New York's subway system is of immense importance to the city's economy, environment, and culture. This innovation helped tame New York's increasingly congested population. The subway system was primarily designed and built as electrically powered transit in 1904, and it is still the same today. Today, the amount of electricity it takes to power the subways annually is about 1.8 billion kilowatt-hours. Four million people travel through the subway per day, and it currently provides 20,000 jobs.

Between 1850 and 1900, the New York population increased fivefold. Steam locomotives were carrying 115 million passengers in 1886, twice the entire population of the United States at the time. Apartments were extremely crowded; there was no running water, no light, or much privacy. Worst of all, filth plagued the city, and the poor were stuffed into tenements, where they developed deadly epidemics like yellow fever, tuberculosis, cholera, and typhus. The solution seemed clear: an urban mass transit system to disperse the population to other areas of the city and alleviate the clogged environment.

The first elevated railway to transport passengers opened in 1870. In the beginning, elevated railways were propelled by moving cables, a system considered deficient later on when they switched over to steam locomotives. The problem was, steam power contributed to the unsanitary living conditions of the city. Soot from coal polluted the skies, and beyond that, the system was extremely loud. Eventually, a multiple control unit, designed and created by engineer Frank Sprague, gave each car its own power unit. This invention changed the way that elevated railways traveled, and it paved the way for the first underground urban mass transit in New York City.

The first subway in New York was designed and created by humanist Alfred Ely Beach. In 1870, he successfully built a pneumatic subway system 312 feet long. Not only was this transit propelled by air, it had a grand piano on board. Many religious people disagreed with the idea of travel being underground and therefore closer to hell. The reason this isn't the current subway system that New York uses is that before Beach could finally gain the approval of politicians

and the public to expand the subway, the stock market turned for the worse and crashed in 1873.

Twenty-one years later, Mayor Abram S. Hewitt passed the Rapid Transit Act of 1894, which finally authorized the development of a municipal subway system. John B. McDonald was a contractor hired by the city as a private entrepreneur to build the subway. The idea proposed was that the city would own the underground railway as well as finance the construction, and it would charge rent. An independent company would operate the subway and therefore keep the profits. However, McDonald faced the problem of raising enough capital to finance the operation. August Belmont, heir to a giant fortune, partnered with McDonald and formed the company still known today as the Interborough Rapid Transit. Their unyielding determination built the subway in four years.

Although four years is rather expedient for such an immense project, there were some roadblocks in the development. William Barclay Parsons, a young chief engineer, was in charge of the design of the tunnels and oversaw its construction. The "cut and cover" technique, which consisted of digging shallow holes and staying near the surface, was applied in the construction of the tunnels. So, basically, workers broke through pavement, dug tunnels, and covered them again.

A huge problem that Parsons encountered was the previous existence of sewer, gas, and water mains that needed to be diverted. There were also issues with the unpredictability of the soil, as it could turn out to be quicksand or solid rock that proved difficult to handle. The use of dynamite, the method used for destroying rock, would disturb the peace by scaring horses and shattering glass windows above. Shoring up and protecting existing construction was also another stressor for Parsons.

The inauguration of New York's subway system finally came on October 27, 1904. The line was a single-track loop under the City Hall. With four tracks, local and express services were provided. The line went from north of the Brooklyn Bridge to Center Street, Elm Street, Lafayette Place, 4th Avenue, Park Avenue, and East 42nd Street. Under 42nd Street, the subway line turned at Times Square and up north under Broadway. The operation was a complete win for the city and only five cents a ride.

Shortly after the inauguration, the city's overcrowding began to vex the subways. They needed to expand—but instead of financing more construction, Belmont took over existing elevated railways, like the Manhattan Railway in 1903 and the Metropolitan Street Railway Company in 1906. In 1913, Dual Contracts was created to start new subway construction. It was decided from the Dual System that more than one company was needed to run New York's subways. The city demanded that Interborough Rapid Transit and Brooklyn Rapid Transit finance the railways or they could lose their leases, and they complied. The significance of this event is that the city was able to use capital from these current companies to finance the \$302 million large-scale construction that was under way.

From the Dual System emerged the Triborough System. This system made it possible for the subway system to run to Brooklyn, Manhattan, Queens, the Bronx, and Staten Island. It expanded New York's underground transit immensely. Connecting the rest of the city was the main goal, and the system runs through those very boroughs today.

The culture surrounding New York's subway has been shaped by its innovation. In 1941, underground transit had a huge role in the war effort. During this time, steel and rubber came under military demand, which automatically put the auto industry at a dead stop. People fled to the subway for their transportation needs. Another important feature was that citizens could seek shelter in it should Germany raid the city with flying bombs. So, it provided a sense of relief to the people of the city during World War II in more than one way.

At the present time, New York City subways, like its city, never sleep. They run continuously, every day, all day, to accommodate the needs of passengers. The life of New Yorkers revolves around the transit system and its dependability.

Talking Movies

The 1927 Warner Brothers movie *The Jazz Singer* became the first feature-length motion picture with synchronized dialogue sequences. This “talkie” would become the most profitable movie to date, but, more important, it augured the potential drawing power of talking movies. This new potential was transformed into a new industry business model.

The history of the movie business is the foundation of today's entertainment business, representing the confluence of communications technology, popular culture, and leisure time. Its birth goes back to American inventor Thomas Edison and the company Eastman Kodak. The process for making moving pictures was patented in 1891 using Edison's camera, the Kinetograph, which took a series of instantaneous photographs on a new Eastman Kodak celluloid emulsion film. The film was played back using a Kinetoscope. Edison introduced the new movie process at the Chicago World's Fair of 1893. Edison was the first to go into movie production at his Orange, New Jersey, laboratory. A great marketer, Edison took these short films to be marketed in a movie parlor known as a “nickelodeon,” which debuted in 1905 in Pittsburgh. Nickelodeons exploded, with 4,000 opening in two years. The potential seemed unlimited.

Edison had a virtual monopoly on the film business until 1908. Still, patent challenges and litigation bottlenecked the whole industry. In 1908, the major companies, including Edison, joined in a combine known as the Motion Picture Patents Company (MPPC). Eastman Kodak agreed to supply film only to MPPC. Even so, a government antitrust suit was not needed, as MPPC failed to monopolize the emerging market, especially as foreign companies entered the competition. The MPPC suffered from its own methodology, which required short feature films, lacked marketing, and ignored customer wants. It was an engineering-driven business model. Movies were limited by MPPC to a reel of film (about 1,000 feet), which

The Broadway Melody was the first talking movie to win an Academy Award for Best Picture. It was also the first all-talking musical. (Universal History Archive/UGC via Getty images)

lasted for about 30 minutes. This was yet another example, like in the case of early autos, of engineering aspects, rather than consumers, defining the market.

European film companies demonstrated the market popularity of feature-length (greater than 30 minutes) historic epic films such as *The Fall of Troy* (1911) and *Quo Vadis?* (1912). The American independents formed together under the Universal Film Manufacturing Company to produce feature-length films in 1912. In 1914, a new film distribution company, Paramount Pictures, emerged to distribute independent films. Another company, Triangle Corporation, proved the market potential of feature-length films by releasing some as long as two-and-a-half hours in length. Such feature films brought the medium into the realm of creative art,

which increased the need for writers such as Anita Loos and Frances Marion and directors such as Lois Weber to work together with producers to please modern audiences.

World War I created a shortage of European silent movies, which led to the rise of Hollywood. Hollywood injected the science of marketing into film production. Prior to 1914, most movie production took place in New York because of Edison's dominance, but the year-round filming opportunities in Hollywood won out. Film production became more consumer oriented as former nickelodeon and theater owners such as Warner Brothers, Universal Studios, and Paramount entered the movie business. Studio production allowed for feature film production. The studios looked to new

themes, such as the comedies of Charlie Chaplin and Buster Keaton, the westerns of Tom Mix, and the adventures of Douglas Fairbanks. Output boomed, reaching over 800 feature films by the early 1920s, with Hollywood studios accounting for over 80 percent of the world's production.

The big breakthrough augured by the success of *The Jazz Singer* was that of sound. The technological breakthrough came out of Western Electric's Bell Laboratories in New York. It was a "sound on disc" system called "Vitaphone." The sound track was not on the film but on a separate 16-inch phonograph. Warner Brothers purchased the Vitaphone and used it on its feature film, *Don Juan*, to add music and sound effects but no dialogue. Prior to this, theaters often hired musicians to provide background music at the theater. While having restricted technical specifications, the Vitaphone did launch the talkie with the 1927 *Jazz Singer*. The talkie turned the financial fortunes of Warner Brothers around, making it competitive with the "Big Five" studios: First National, Paramount, MGM, Universal, and Producers Distributing. Like so many pioneers, the Vitaphone inspired new inventions because of the market success of talking films. Within a few years, better sound-on-film processes emerged, such as the Fox Movietone and RCA Photophone system.

The use of sound caused major changes in the market. More complex mystery films evolved, such as Alfred Hitchcock's *Blackmail* (1929). Of course, the classic Hollywood musicals appeared, such as *The Broadway Melody* (1929) and *42nd Street* (1933). Wall Street took notice, with a major loan by Goldman Sachs to Warner Brothers. Warner Brothers pioneered the first all-color, all-talking movie, *On with the Show* (1929), which would become the industry standard. As the cost of producing rose, advertising increased to improve the gate take.

Traffic Light, Electric

As cars became ever more prominent in the early 20th century, the invention of the electric traffic light was clearly inevitable. The electric traffic light brought a much-needed order out of the chaos that arrived with the technology that is the automobile. As the popularity of the automobile rose in society, the invention helped promote safety and efficiency on the streets.

In the early 1900s, roads in the United States were becoming crowded with people out and about in various modes of transportation, whether on foot as plentiful pedestrians, pedaling on bicycles, or riding in cars, which often still made use of horses. The period was a unique time in which both horses and automobiles shared the same pavement. The number of accidents involving automobiles grew, and consequently, so did fatalities. While the number of carriages began to dwindle, the boom in the automobile industry was just getting started.

The dangers posed by the increasing number of cars led to new ways for society to navigate the streets. These included traffic islands in 1907, the division of streets with paint in 1911, and signs that disallowed left turns for cars in 1916. With the spread of automobiles, traffic police appeared in cities to combat problems, particularly in intersections. They conducted the flow of cars by hand, but traffic lights run by gas also became popular in the United States. They had originated in London and were first used on December 9, 1868.

There were many attempts made worldwide to create the first electric traffic light, but on August 5, 1914, the first went up in Cleveland, Ohio. At the cross streets of Euclid Avenue and East 105th Street, a pair of green and red lights were placed at each corner of the crossing, thanks to the inventor James B. Hoge. Not only did these run electrically, but Hoge

designed the traffic lights with the fire and police departments in mind. His lights were controlled nearby from fire or police boxes, also known as substations, and manually switched by traffic police officers. Hoge also created a system of signals for communication between the substations and the actual fire and police stations.

Triode Tube

The triode tube is a vacuum tube capable of amplifying an electronic signal. Patented in 1908 by inventor Lee de Forest (1873–1961), it consists of an evacuated glass case, or envelope, that contains three electrodes. The triode was an important invention for radio and electronics and was the precursor to the transistor.

On November 13, 1906, de Forest was granted a patent for his first Audion tube, which contained only two electrodes—a negatively charged cathode and a positively charged anode. This device was based on an earlier tube design by British electrical engineer J. A. Fleming (1849–1945), appropriately called the “Fleming valve,” or thermionic diode.

Like the Fleming valve, the Audion allowed electric current to flow in only one direction. De Forest began experimenting with the Audion’s design. He added a third electrode in the form of a metal screen between the cathode and anode, which he called the “grid,” using a setup consisting of an evacuated glass tube connected to a 22-volt battery and a set of headphones. When current was applied to the vacuum tube, de Forest could hear clicks through the headphones.

De Forest discovered that by applying a very small current to the grid or changing its electrical polarity, he was able to control the amount of current reaching the anode. The triode could also be completely shut off, thus functioning like a valve. On February 18, 1908, de Forest received a patent for this new version of the Audion, the first triode tube, although it would not be called by that name until 1919.

De Forest used his triode to detect and rectify (change alternating current to direct current) radio signals, but it was not until 1911, when electrical engineer Edwin Armstrong (1890–1954) realized that the Audion could amplify electronic signals, that the triode became of widespread interest for telephone and telegraph purposes. In 1912, de Forest sold the rights for the triode to the American Telephone and Telegraph Company, a decision that he would later regret.

De Forest’s early triodes were prone to feedback, which produced a howl or squeal in the headphones. Other engineers worked on reducing the noise problem, notably Finnish engineer Eric Tigerstedt (1887–1925), who refined the triode’s design and improved its amplification by rearranging the electrodes and making several improvements that reduced interference with the radio signals.

Triode tubes were used commercially throughout the 20th century, although most were replaced by solid-state electronics. In recent years, audiophiles and electronics hobbyists have created a renewed demand for triodes.

Turbine Engine, Gas Powered

The engine is arguably one of the most “American” inventions of all time, powering the treks of Americans from the country’s early days of expansion. While the steam turbine engine contributed greatly to the movements of Americans, the shift to a gas-powered turbine engine greatly improved the ways in which both material and people were transported. Not only was the gas-powered turbine engine much more efficient, it also benefited from being simpler in design and required smaller machinery to operate.

The theory of a turbine engine existed long before it ever materialized. Around the 16th century, Leonardo da Vinci drew a prototype for what resembles a gas engine. His invention involved a fire that would blow hot air, in turn rotating a gear and set of chains. The first emerging turbine engines, though, were run by water, or more specifically, by steam, controlled by temperature, pressure, and direction. A jet of steam was aimed in such a way that it would rotate turbine wheels. The blades on the turbine wheels provided even more efficiency, as the steam would be carried through and push the assembly with more ease.

As years went by, the steam turbine engine was regarded as the choice for power, especially for ships. By the 20th century, the invention saw modifications to further improve its performance. These changes included an alteration in shape for the blades to reduce friction, therefore maximizing the amount of power gained from the engine to do work. While the updates were progress on the technology, a more significant development was the introduction of the gas-powered turbine engine.

In 1899, Charles G. Curtis developed the gas-powered turbine engine, which would soon replace the steam turbine engine in numerous ways. Curtis was also among those who led the way toward a gas-powered turbine engine. Even after the modifications toward a better steam turbine, at most, the useful energy from it was 15 percent of what it generated. About 60 percent of the energy created by the steam turbine is lost, disappearing simply as undirected evaporation and a considerable amount of heat loss.

The gas-powered turbine does not use steam, and it utilizes a fuel for combustion to create mechanical

motion. Unlike the thermal energy in steam, the fuel for gas turbines has greater thermal efficiency, or the amount of work produced from the amount of heat generated. Another case for the gas turbine over the steam turbine was that temperature and pressure are proportional to thermal efficiency and overall mechanical work, and so, the higher the temperature and pressure of the system, the higher the system’s efficiency. Temperature and pressure of this magnitude proved difficult for steam to reach, while gas has an easier time of it.

In addition, a steam turbine engine required numerous bulky apparatuses to support its energy production, such as boilers and furnaces. Not only did these pieces of necessary equipment take up too much space, they were also heavy, which was not favorable when placed on a ship. The inevitable maintenance and repair of these machines grew quite expensive, and in comparison to their output of energy, they became impractical. The gas-powered turbine engine lessened the required space and weight, and it was simultaneously more efficient in cost and energy.

Washing Machine, Electric

The electric washing machine has been a household staple since its first introduction at the turn of the 20th century. Clothes were first washed by hand and then

with simple machines requiring manual labor, but the wash became significantly less of a hassle with the electric washing machine.

In ancient times, washing clothes often involved natural sources of water such as rivers or lakes, and an abrasive surface, like a rock. The most well-known tool used for doing laundry before the washing machine arrived was the washboard. Typically made out of metal (although glass has also been used), washboards helped change the way people washed clothes. This could be done at washhouses, or places in town in which water was sourced; washing clothes required being away from home. It became the norm for women to be relegated to cleaning the family's clothing, and the idea that laundry was solely the wife's job promoted bonding between women, as they would come to wash their items at the washhouses and discuss their lives.

A mechanical washing "machine" was invented in the mid-1800s needing less manual labor than washboards but still requiring physical movement. It consisted of a drum with blades inside that would be rotated by hand via an attached handle.

In the early 1900s, the way people did laundry soon changed. Washing machines with cranks for spinning were by then seen as outdated, and people were looking for ways to modernize how laundry was done. In 1908, the Hurley Machine Company of Chicago introduced the electric washing machine, the Thor washer. While many may dispute who made the first electric washing machine, the Thor washer was still no doubt a key contribution. Being the very first to be commercially sold in the United States, the washer was designed by Alva J. Fisher, an engineer at the company.

The Thor washer was driven by motor rather than manually by the user like previous washing machines. The machine had a tub, and inside was a large, hollow cylinder that would spin a certain number of complete revolutions as the clothes inside tumbled in soapy water. After reaching the right number of spins, the machine reversed direction, which, along with the blades within that lifted the clothes apart, was meant to prevent clothes from clumping altogether. The invention, as Fisher had aimed for, provided a more efficient and less tedious way for women to wash clothes.

Welding, Alternating Current

In 1919, Claude J. Holslag invented a new type of welding using the power of alternating current. A resident of Peekskill in the county of Westchester, New York, Holslag worked for the Electric Arc Cutting and Welding Company as well as for the New York Central Railroad. He was involved in World War I as an associate of the Emergency Fleet Welding Committee and, as such, was part of the development of electrode and alternating current welding.

Holslag won the Samuel Wylie Miller Medal in 1939 for carrying on his work in the American Welding Society, where he eventually owned 200 patents. Holslag also wrote papers on welding and authored the *Arc Welding Handbook* in 1924.

What Holslag discovered was that when the alternating current is high, the electrical arc is able to cut through the metal depending on the arc's length. This is an extremely difficult weld, because the right amount of electrical power has to be chosen for each type of metal being welded. Alternating current (AC) is different from direct current (DC) because the electrons go back to the electric source; it was a major advancement for welding technology because AC has a stabler arc for welding. An unstable arc means that its electric current keeps moving around and does not stay in one area; this is called "arc blow." The weld has to keep an arc that is stable enough; otherwise it will not come out well enough for the standards of the American Welding Society (AWS).

Holslag died on June 11, 1945, at the age of 60. At this time, he was president of the Electric Arc Incorporation in Newark, New Jersey. Holslag had played a major role in the creation of the American Welding Society. The board members and friends of AWS awarded Holslag for his thoughtfulness, honesty, and honor.

Welding, Automatic

Welding is a method of joining pieces of metal together through a fusion process using heat and gases. Automatic welding was invented in 1920 by P. O. Nobel, who was then working for the General Electric Company, which gave him the background to create a new type of weld. He developed it by using the arc voltage to control the feed rate of the electrode in direct current (DC). DC flows from the power source in one direction and does not go back to the machine, which only happens in alternating current. One can use either direct current or alternating current for welding, depending on what type of weld is desired.

Automatic welding was first used to help build up worn motor shafts and crane wheels. The automobile industry used it to make rear axle housings for vehicles. This was an era when welding became popular because industries were growing that increased the demand for joining metals together. Arc welding uses arc voltage and electrode wires and was mainly used to repair certain metals.

Automatic welding was one of the first welding styles that required electrodes. It required a long electrode to keep feeding into the arc, and the nozzle fed off the electrode, which allowed the weld to keep going. The nozzle contains a passageway that is connected to a source of gas or vapor supplied through an automatically controlled valve. Most welders had to adjust their angle of weld depending on what type of welding was performed.

Automatic welding prompted the use of shielding gas, which protects the weld from the effects of too much oxygen and nitrogen in the atmosphere. This makes the weld more durable and stable. Before the use of shielding gas, brittleness was a huge problem when welding two metals together. A solution of hydrogen, argon, and helium is used as the welding atmosphere in automatic welding.

3. The Great Depression and World War II (1930–1945)

OVERVIEW

As the United States lay mired in the depths of the Great Depression, Franklin Roosevelt assumed the American presidency in March 1933. For three years, the country had waited for the return of the prosperity that President Herbert Hoover had promised was just around the corner. And yet, in reality, Hoover, the “Great Engineer,” a man who had made his reputation feeding Europe in the aftermath of World War I, had been unable to turn the tide as the Great Depression enveloped the nation. Into the void, the beneficiary of an electoral rebuke that would haunt Hoover for the rest of his life, came Roosevelt, who, exuding an optimism that belied both his own genuine concerns as well as the nation’s true economic situation, told the American people that they had “nothing to fear but fear itself.” The contrast could not have been more telling. Yet the government that Roosevelt was to lead found itself forced to seek answers to previously unasked questions. Some of the answers would ultimately result in efforts to address the impact of previous inventions and innovations that had fueled the economic growth of the first decades of the 20th century but which had also, in their own way, contributed to the economic downturn that had become the Great Depression. From a series of agricultural advances that made overproduction an often devastating fact of farmers’ lives to technology that made investing and the stock market seem more like a game than a process on which a family’s economic fortunes could be founded, Roosevelt’s New Deal programs would ultimately seek to harness and redirect existing technology while also encouraging new inventions and approaches, all with the goal of helping a nation that

was struggling to recover from the greatest economic downturn in its history.

No one was more innovative than Roosevelt. Approaching the governing process like an inquiring scientist, he declared, “It is common sense to take a method and try it. If it fails, admit it frankly and try another. But above all, try something.” His willingness to risk failure in pursuit of solutions, an approach not unfamiliar to the scientists and inventors whose efforts had sparked earlier innovations, represented a different approach to government, but one aptly suited to the distinctive needs of Depression-era America. Consequently, while scientists and inventors were moving ahead, creating new items and refining existing ones, a newly empowered government began to undertake its own innovative efforts in an attempt to respond to a society in need. Indeed, central to the New Deal was the development of innovative and creative governmental programs that marshaled and harnessed technology, both old and new, in an effort to serve the American people.

The New Deal Spawns a Technological Revolution

Few things better demonstrated this partnership of the 1930s than the New Deal’s creation of the Tennessee Valley Authority (TVA). Using modern technology and advanced engineering skills to harness the power of the Tennessee River, the complete project transformed a whole region of the country, ending literally decades of darkness and exposing residents to countless aspects of American life that they had been denied.

The TVA had its roots in a pre–World War I plan to construct a dam in the Muscle Shoals, Alabama, region, a place where the Tennessee River dropped 140 feet

over 30 miles and made it all but impossible for ships to travel farther up the river. In 1916, the federal government acquired the land, intending to build a dam whose ultimate purpose would be to provide sufficient power to produce explosives needed for the impending war effort. The war ended before the initial construction had been completed, and with its original purpose rendered moot, the land became the subject of a decade long tug-of-war over who would have control of its future use. Nebraska Senator George Norris spent much of the 1920s seeking to maintain public control of the area while pushing a plan to have the federal government develop it. His efforts had been stymied by a recalcitrant Republican Congress, but when Franklin Roosevelt, whose personal interests included regional planning, conservation, and public utilities, assumed the presidency, he threw his support behind Norris and pushed the Tennessee Valley Authority Act through Congress in the spring of 1933. The law was intended to improve the navigability of the Tennessee River, provide for flood control and reforestation of the area, and help with agricultural development in the area while also aiding in national defense through the creation of facilities that could produce nitrate and phosphorus for the government. Completion of the project, whose reach, given the fact that the Tennessee River flowed through seven states, would be extensive, represented a major engineering feat. But beyond that, the legislation called for the TVA to improve “the economic and social wellbeing of the people living in the river basin.” It was in response to this part of the legislation that FDR issued an executive order creating the Rural Electrification Administration (REA). The REA’s purpose was to bring electric power to rural areas that had not previously been served as private business did not think there was sufficient profit potential. The REA helped create over 400 rural electric cooperatives that brought electricity to almost 300,000 households by 1939. Too, the encouragement of the REA coupled with the example offered by its success led some private utilities to expand their services into rural areas.

The impact of this increased electrification was not limited to its recipients, for the access to electricity left them anxious to use the time- and energy-saving appliances that the electricity powered. Consequently, local appliance merchants also benefited from this advance. Indeed, the TVA set up the Electric Home

and Farm Authority (EHFA), which helped farmers secure low-cost financing that allowed them to purchase appliances like refrigerators, water heaters, and electric ranges at reasonable prices. All of this served to benefit the appliance manufacturers and the electric companies while also allowing a sizeable part of the nation’s population to join its fellow citizens in enjoying an improved quality of life. In the end, the projects ultimately represented an innovative effort that combined governmental resources and engineering expertise, both undergirded by a desire to include a greater number of citizens in the American experience.

No less impressive or significant were the efforts being undertaken out west, where the nation’s engineering corps put the same impressive talent to work in designing and constructing the Hoover Dam. That project, which created the largest man-made lake in the country—that, when full, held enough water to cover the state of Connecticut to a depth of 10 feet—presented unprecedented challenges to the Bureau of Reclamation’s engineers. However, upon its completion in 1935, the dam, which had become an unexpected tourist attraction during its construction, was both a marvelous demonstration of American engineering capability and a pioneering effort in the utilization of hydroelectric power. A monstrous structure, it processed the same amount of water as flowed over Niagara Falls, and the amount of concrete used to build the whole thing could have paved a road from New York City to San Francisco. The dam was the linchpin of a larger, multifaceted project aimed in part at irrigating, as well as helping with the growth of, small farms. In addition, it was designed to protect Southern California as well as Arizona from the floods for which the Colorado River was, unhappily, known. In a triumph of innovation and technology, it achieved all of those goals and more. Indeed, completed while the country was still struggling to emerge from the Great Depression, the Hoover Dam became a symbol of what the nation, undaunted by its recent challenges, could still achieve.

Reshaping American Life through Technology Large and Small

While the major projects like TVA, the Hoover Dam, and the aviation- and military-related advances whose importance would be so evident in just a few years, as

well as the other innovative New Deal programs that were reshaping the American economic landscape, got most of the attention, American ingenuity and creativity were in no way limited to “big ticket” items. Indeed, despite the nation’s economic trials, the United States witnessed the invention and development of countless items that were deeply appreciated at the most basic of human levels by a populace bruised and scarred by the Great Depression. In fact, in the midst of the Great Depression, any invention or development, no matter how small, that could help boost the national morale was particularly welcome. One such advance was the introduction in 1935 of canned beer, no small development in a country less than five years removed from Prohibition. It was also one that impacted the social dynamic, as people no longer needed to go to the local bar for a beer. Another item that made life a bit less onerous was the board game Monopoly. While a variety of small-scale versions had floated around since the early 1900s, Parker Brothers unveiled its version in 1935, and it became a national—and ultimately, an international—phenomenon, allowing a nation struggling to make ends meet to enjoy playing the role of the wealthy banker, real estate developer, and entrepreneur while taking financial risks that had no consequences.

Too, the introduction of the electric razor by Jacob Schick in 1930, an invention further refined by the Remington Company, which introduced its own brand in 1937, was a boon to men across the country. Meanwhile, the development of suntan lotion reduced the sunburns that often made a day at the beach a mixture of pleasure and pain, and the polarized sunglasses that debuted at this time also helped make the beach experience, one that could now include activities involving the newly introduced beach ball, all the more enjoyable.

General Electric’s introduction of the garbage disposal, as well as the debut of a new style of electric blanket, one in which the heated blanket rested on top of an individual, was welcomed in homes across the country. At the same time, DuPont’s development of nylon as a synthetic substitute for silk morphed into the very popular nylon stockings that were introduced in 1939—just in time for their production to be curtailed when the war effort required all nylon to be used for parachutes and not the newly stylish stockings. Neoprene, a synthetic rubber developed during the

1930s, suffered a fate similar to nylon, for its military uses precluded its commercial development until after the war. No less well received and appreciated by the nation’s long-suffering homemakers and cooks were the frozen foods invented by Clarence Birdseye at the start of the decade—and, of course, the creation of the chocolate chip cookie as well as soft-serve ice cream helped bring smiles to countless faces young and old. Teflon and freeze-dried coffee, both invented near the end of the decade, would also do much to ease the future burden on homemakers. The 1930s also saw the development of Plexiglas, Lucite, Teflon, latex rubber condoms, and tampons, all of which had a substantive impact on the daily lives of many Americans. So too did the shopping carts that made going up and down the aisles of the now well-established supermarkets a much easier task. In addition, clear adhesive tape and cellophane, originally intended for use in grocery stores, soon became a staple in the American home, and their use was aided by the development of an easy-to-use dispenser. And, of course, after years of experiments and trials, RCA’s unveiling at the 1939 New York World’s Fair of the first practical black-and-white TV set, a bulky machine to be sure, heralded what would, in the aftermath of World War II, prove to be a veritable cultural revolution. Yet, while many of the new inventions and innovations were beyond the reach of the masses who were still suffering, some addressed the economic divide that the Great Depression had revealed. Foremost among these was the opening of the first Laundromat. Recognizing that only the wealthy and those with electricity could have their own washing machines, John F. Cantrell developed the idea of “renting” the use of such a machine for an hour. With four machines in operation, Cantrell opened the first Laundromat, what he called a “Washateria,” in Fort Worth, Texas, in April 1934.

Modernizing Entertainment: From Radios to Roadsters

Modern communication continued to develop at an impressive rate with new developments large and small affecting the way people communicated in the broadest sense. In 1930, newscaster Lowell Thomas offered the first regular radio network newscast and in 1931 the first commercial teletype debuted. Early in

the decade, Ford began to include radios in some of their cars, while the FM radio was introduced in 1933. Indeed, radio was taking off in the 1930s, so much so that the government, seeing the need for its regulation, enacted the Communications Act of 1934, which created the Federal Communications Commission (FCC). As the Mutual Radio Network began operation that year, it was reported that half of all American homes had radios, and, of course, President Franklin Roosevelt had already begun to harness its potential political power through his “fireside chats.” Radio’s power was also reflected in the emergence of the CBS *World News Roundup* in 1938, an event met with a much more restrained response than that given to Orson Welles’s *War of the Worlds*, the radio drama that panicked the nation while also demonstrating the medium’s clear, but as yet not fully tapped, power. Beyond radio, that period also saw the introduction of stereo records as well as the first tape recorder able to be used for broadcasting. While its true impact would not come until later, the development of the electric guitar, which debuted in the 1930s, would subsequently revolutionize the music world. The film industry was enhanced as Disney adopted a new three-color Technicolor process for its cartoons, an approach that was adopted by live-action films just a few years later. Too, the film *Napoleon* moved the film industry into uncharted territory as it debuted stereophonic sound, while Disney offered the first full-length cartoon when *Snow White* arrived on the screen in 1937. The invention of the photocopier in 1937 as well as the emergence of the ballpoint pen both played a continuing role in communication, but they, like the advent of fluorescent lamps for interior use and the unveiling of the desktop phone, were, in fact, more typical of the growing number of developments that made office work more comfortable, efficient, and productive. And while years of continued research, refinement, and developments lay ahead, efforts such as at Bell Labs and the Massachusetts Institute of Technology were underway to develop and build prototypes of the computers that would revolutionize the world a few decades later.

At the same time, many of the advances in the New Deal era were simply refinements and improvements of existing products. This was very much the case in

the world of photography, which continued its evolution into the 1930s with the introduction of stop-motion photography, Polaroid photography, the zoom lens, the light meter, and Kodachrome color film. Too, Kodak introduced 8-millimeter film for the ever-popular home movies. And, of course, few things reflected the nature of American life better than the latest round of car-related developments. As noted, some of the high-end cars rolling off Ford’s assembly lines in the early part of the decade featured radios, but safety concerns raised by the ever-greater number of cars on the road led to more practical advances like the development of the road reflector and the introduction of the yield sign. Too, with the increasingly crowded urban streets, the ever-growing number of cars on them, and the increasingly active government’s need to fund their efforts, the development of the parking meter, which made its debut in 1935 in Oklahoma City, Oklahoma, was inevitable.

Meanwhile, other scientific advances included the development of the black light as well as the Richter scale to measure the severity of earthquakes. At the opposite end of the scientific measurement spectrum, there was the development of the pH meter, which could measure the acidity of liquids, a substantive aid in health-related issues.

Entertainment during the Great Depression was the ultimate double-edged sword, as tight budgets limited what people could afford, and yet the need for diversion and things that could lift people’s spirits as well as the nation’s morale was, in many ways, more important than ever. At the same time, those realities did not stop the ongoing efforts to improve existing options while developing new ones. The development of the chairlift reflected the increasing popularity of skiing for those who could afford it in those troubled times, while the development of the bass guitar in the mid-1930s heralded a post-World War II musical revolution.

Technology Turns to the War Effort as World War II Looms

Of course, unbeknownst to the inventors and developers at the time, many of the advances that arose during the 1930s, products of a country stuck in the throes of

the Depression, would ultimately have an incalculable impact on the nation's efforts in World War II. Indeed, the early part of the decade saw a new round of developments in the aviation field, with the invention of both the first jet engine and the first turboprop engine. In looking back, it became clear that, as one analyst noted, "The 1930s saw a tremendous period of growth in aircraft technology—all-metal skin, enclosed cockpits, retractable undercarriages and increased armament capabilities." Too, in 1939, as the New Deal drew to a close and World War II loomed, the first helicopter arrived on the scene. In fact, many of the inventions of the 1930s, coupled with ongoing developments in existing aircraft, were critically important in World War II. As the nation moved deeper into the 1930s, the potential threat posed by the European war and Adolph Hitler's Nazi regime could not be ignored. While still in economic distress, Americans showed little desire to get involved in what most saw as a European conflict. At the same time, however, the United States did continue to develop armaments that could be used if peace efforts failed. Indeed, as the decade rolled to a close, considerable amounts of American technological expertise and talent were being directed to developing things that might help in that effort. It was not always an easy process, for a variety of postwar congressional investigations into U.S. involvement in the Great War had raised questions about the role of the American arms merchants and financiers in the U.S. entry into that earlier conflict. Those questions, coupled with the deeply unsatisfying end of that conflict with the failure of the United States to ratify the Treaty of Versailles and the U.S. absence from the League of Nations, did nothing to make the American people anxious to get involved in another war in which their interests did not appear to be directly threatened. But that sentiment did not stop the development of war materials, whether with an eye to sharing them with others whose efforts could preclude future U.S. involvement or simply to be at the ready should the United States ultimately become involved. Large amounts of time and money were being invested in the development of new items as well as the refinement and improvement of existing ones.

In fact, during the period between the end of World War I in 1918 and the U.S. entrance into World War II

in December 1941, the nation's military aviation capabilities and equipment underwent a complete transformation. The open-cockpit biplanes, usually made of wood, which had characterized World War I aerial efforts, had been replaced by all-metal monoplanes with four times the horsepower of their First World War predecessors as well as the ability to fly at altitudes of 30,000 feet. Indeed, the planes developed in the 1930s, aircraft that were at the heart of the wartime American Air Force, were technological marvels able to reach speeds of almost 250 miles per hour, over twice that of the standard World War I planes. In addition, the development of radar, the newly developed, gyroscopically driven flight instruments, and the electrical cockpit lighting allowed not only for nighttime operations but also for missions to be undertaken despite adverse weather.

Interestingly, many of the aviation developments of the 1930s that would prove so important to the war effort of the 1940s had their roots in the civilian air racing that was popular in the 1920s. A highly entertaining activity during the Roaring Twenties, many of the high specialized racing biplanes were built by the Curtiss Company for the U.S. Army Air Corps and Navy. The innovative designs that emerged at that time would be further refined and adapted to the wartime needs of the United States, allowing individuals like Lt. James Doolittle, who was a champion racer in the 1920s, to become a star fighter pilot with the new equipment used during the war.

Meanwhile, the commercial side of aviation was also ready to move ahead in the 1930s. However, despite the fact that the needed technology was in place, the aeronautic community was essentially grounded by the nation's economic woes. Amid unprecedented levels of unemployment and poverty, advancements in commercial air travel were not at the top of the nation's economic priority list. However, as the government advanced and expanded its support of airmail carriers, it was, however unwittingly, laying the groundwork for expanded commercial operations. Indeed, the passage in 1930 of the McNary-Watres Act began the transformation.

Seeking to enhance its airmail delivery services, the government altered the way it compensated its airmail contractors, shifting from a system where

payment had been based on the weight of the deliveries to one paying according to available cargo space. This served as an obvious incentive to operate large aircraft. As a further incentive, the government also offered a bonus to the mail deliverers operating multi-engine planes as well as planes that were equipped with the latest and most up-to-date instruments. This encouraged the nation's developing airlines to increase the number and size of their aircraft, ones that were capable of—and would profit by—carrying more passengers. The whole policy launched an industry-wide race as United Airlines and Transcontinental and Western Airlines (TWA) contracted with Boeing and Douglas Aircraft, respectively, to design and build the necessary aircraft. Too, refusing to be left behind, American Airways also contracted with Douglas Aircraft. This early battle for control of the skies led to a full-scale competition, which resulted in the development of the Boeing 247 and the Douglas Commercial One (DC-1). It was soon followed by the DC-2 and the DC-3, which, by the end of the decade, was carrying 90 percent of commercial air traffic worldwide. Indeed, its broader utility was also evident in the fact that 10,000 were built to serve the U.S. Army in World War II. Meanwhile, given that many routes were over water and that airplane bases were cheaper to construct at sea than airports, Pan Am developed a fleet of seaplanes, and by the mid-1930s, the company had routes traversing both the Atlantic and the Pacific Oceans.

All these advances ultimately helped make commercial aviation a comparative bright spot in the sputtering 1930s economy. But at the same, the aviation industry was also helping, however unintentionally, in the effort to advance the nation's military capabilities, a need that grew ever greater as the situation in Europe grew more threatening. Indeed, the European situation forced the United States to rethink the aviation policies that, since the end of World War I, had seen the airplane as primarily a defensive weapon whose only real responsibility would be to defend American shores.

However, as a growing number of Army Air Corps leaders came to envision the offensive possibilities of the airplane, efforts were undertaken to investigate and develop appropriate aircraft, with the B-17 bomber being the prime example. And in its own way, its development represented the intersection of the commercial

and the military development efforts, for when the Boeing 247 was rendered obsolete by the development of the DC-2 and DC-3, Boeing instead focused on a design competition sponsored by the army that sought to develop a new multiengine bomber intended for coastal patrol. Boeing's entry in the competition, a four-engine giant labeled the Boeing 299, made its first test flight in June 1935. The 299 not only won the competition but proved itself capable of outflying any other fighter plane, a status that quickly earned it a major contract with the Army Air Corps. And, of course, efforts continued into the 1940s and during the war itself to further develop the combat aircraft that would prove so important to the nation during World War II.

Wartime Inventions that Enhanced Postwar Living

As FDR announced that he had shifted roles from “Dr. New Deal” to “Dr. Win the War,” the nation increasingly focused on preparations for war. While this resulted in the development of new items like the jeep, a vehicle that would prove critical to overland travel in the European and African theaters (and would, of course, become a constant sight on the highways of postwar America), and new weapons, including napalm, flamethrowers, and smoke screens, not all the inventions and new developments that emerged in the early 1940s aided the war effort. Rather, as has often been the case throughout history, creativity mixed with adaptability and some plain old dumb luck led to some discoveries whose real true impact would be realized only in the postwar world. A prime example was the development of that all-purpose material, duct tape. Originally developed as a water-resistant tape intended for sealing ammunition cases, its many other uses were soon recognized, and it became a necessary part of anyone's home repair kit. Other discoveries of the period that would become a part of postwar life were Silly Putty and the inimitable Slinky. Too, new products developed just before the war, like plastic wrap (used instead of tinfoil), cardboard milk containers that replaced glass, and innovations like fiberglass, polyester, and plastic that would be central to life in the 1950s, also had their roots in war-based experimentation and development. And, of course, there was also penicillin. Originally developed in England in 1928, the British

worked on it over the next decade and a half, but problems with the development and a lack of resources necessary to produce it on a large scale hampered them. When the British contacted American pharmaceutical companies about it, they were interested but leery of the demands that production would make. Finally, the drug's potential value became so clear that the U.S. War Production Board assumed oversight of its production in 1943—clearing the way for a drug that would revolutionize postwar health care.

The advent of World War II continues to color the debate about the impact of the New Deal on both American economy and society. Yet as we look back on a nation that emerged from the Depression of the 1930s to build a war machine that helped save the world from the threat of fascist domination, there can be no denying that at least part of the nation's rebound can be attributed to science and technological advances coupled with multifaceted governmental innovations. Some of these clearly had an obvious impact, while others were not only more subtle but would not, could not, be fully recognized until sometime in the future. That is certainly true regarding the many military-based advancements, most of which their developers hoped would never be needed but were determined to have ready if they were. Indeed, as the New Deal began to fade into history and the 1930s slowly made way for a new decade, the nation looked ahead to a still-uncertain future. And yet it did so while able to take comfort in the fact that, in no small part due to shrewd use of its scientific, technological, and innovative abilities, it had proved its resilience in responding impressively to an unprecedented crisis. There was no reason to believe that it could not do so again.

This singular period, one that saw the United States emerge from the depths of an unprecedented economic depression to a position of unparalleled world leadership, came to an end in August 1945 when one of the most momentous scientific achievements of all time, the atomic bomb, was unleashed and ended World War II. While its impact was undeniable, so too was the potential for further devastation clear. Indeed, as the world cast its gaze on its war-torn self, it could also contemplate a future dedicated to recovery. Meanwhile, the United States could look back on a decade and a half of momentous change and accomplishment. Still, it had to recognize its responsibility in taking the

lead to confront the unprecedented challenge of how to best harness and direct—for the best interests of both a very different society and a very different world—the incredible power that had been unleashed with the atomic bomb.

Alaska Highway

The Alaska Highway is a 1400-mile stretch of highway that connects Alaska to the contiguous United States through Canada.

In the 1920s, the U.S. Bureau of Public Roads director, Thomas MacDonald, envisioned a connecting roadway between the United States and Canada, which would be Alaska's link to the contiguous United States. Canada initially saw no value in the project, stating that the only Canadians who would benefit from the roadway numbered in the low thousands. The Canadian government agreed to construction in 1929. Progress halted in the 1930s because of the Great Depression, but the road was finally completed in 1942. The attack on Pearl Harbor was the inciting event for the completion of construction, for the motives of the United States and Canada were more aligned than in previous discussions due to the war effort.

Contributions to the war effort included key access points to airports and military equipment. Supplies were shipped from Great Falls, Montana, to Fairbanks, Alaska, and the road was the prime transportation route in 1943. The highway assisted in saving more lives in the armies of Canada, the United States, and Great Britain, and led to a more refined and quick war. The highway is also seen as a key factor in the postwar

Two construction workers walk across a half-built bridge over a tributary of the Peace River in Canada. Built in 1942 to connect the contiguous United States to Alaska, the Alcan Highway had been proposed as early as the 1920s but became more important during World War II. (Library of Congress)

development of the Alaskan and Northern Canadian regions.

The dedication of the workers to complete the task in such rugged and cold terrain did not go unnoticed. A 1942 *Times* article reported that nearly 40 percent of railway workers were African American, saying that they had a significant role in the creation of the highway. Brigadier General Clarence Sturvaden commissioned the all-black Regiments 93 and 97 to work on segments of the road, because other generals were hesitant to supply them. The 93 and 97 had to do manual labor and with more effort than more adequately equipped regiments would have had to.

The Alaska Highway had been planned to be 1700 miles long, but with reconstruction and rerouting, it became slightly shorter. It was also originally highly

impractical due to steep grades, quick switchbacks, and rocky terrain. The public was told that the roadway was finished in 1942, but it was not. While the road has been straightened and paved since, it is still not a journey for the fainthearted. A stimulus of tourism to the area, increased populations in remote Alaskan and Canadian cities, and increased economic activity proved the route integral. Mines opened, tourism activities drew in revenue, and consequently, nature was adversely affected.

Environmentally, the highway disturbed the area's pristine prewar conditions. Bulldozers and asphalt invaded the habitat of fauna and flora, causing a heavy environmental footprint in the Alaska-Canada region. Dumps lining the route that contained metal building equipment and wasted gear and materials raised

complaints from citizens to the Alaska Highway Commission. Thousands of creatures live nearby and are affected by the highway, not including the thousands of human emigrants it brought to the land.

The Alaska Highway could also be called the Pan American Highway because unofficially, it stretches from the northernmost tip of Alaska to the southernmost tip of South America.

Primary Document: Excerpt from Ruth Gruber's Study of Highway Routes to Alaska (1941)

In 1941, the secretary of the interior appointed photojournalist Ruth Gruber as field representative to the Alaska Territory. Her job was to complete a study of the Alaskan frontier and report on natural resources, homesteading opportunities, and the Alaskan highway. A Jewish activist, she thought Alaska might be a good place to relocate Jewish refugees from Nazi Germany.

Stretching up in the distance, as we neared Talkeetna, was Mount McKinley. The tallest mountain peak in North America, it was a sculpted mass of ice and snow and rock.

Once again I became aware of how empty this land was, how easily newcomers and refugees could have lived here, liberated from the fires burning in Europe . . . Peggy Gordon . . . owned a successful dress shop in midtown. Sweltering in the heat, I dropped in and chatted with her. Because laundering was so costly (blamed like everything else on the high cost of transportation), it was cheaper for me to buy a new white blouse each week from Peggy than to have the one from the previous week washed and ironed.

Peggy had spent twelve years “Outside”—in the lower forty-eight—bringing up her son, who was now thirty, and her daughter, who had been “Miss

Fairbanks.” Moving back to Alaska, Peggy became the head of the Women’s Club in Anchorage. But in Fairbanks, where she now lived, she was too busy running her shop to go to meetings.

“I’m really in love with this town,” she told me. “The people here are so warm and democratic. Everybody digs in. It’s awfully hard on women though. They have to keep the fire burning all winter. The days are short, and it gets so cold, and there is so much to do, but there is a real heroic spirit.” She nodded, watching me jot her words in my notebook. Then she went on. “The real trouble with Alaska,” she said, lowering her voice confidentially, “is that Alaskans think they are so much better than everyone else who comes up here. They think they are just the best people in the world.” She conjured up an image of Alaskans standing with one leg on the gravy train and the other leg free to kick everyone else off.

Her husband, Frank, a small man with a shock of white hair and a Scottish brogue, entered the shop. He was a member of the legislature, and for long intervals left Peggy alone while he worked on bills and committees in Juneau. He joined the conversation as if he were making a speech.

“I’d like to see ten or twenty thousand people come up here when they build the Alaska Highway.

But the think I have against your boss Ickes is that he wanted to bring six hundred thousand refugees here."

"No, Frank," I said to the legislator, "the bill Ickes tried to introduce would only have brought five thousand Jewish refugees a year to Alaska." I shook my head, thinking, *This is the way anti-Semitism takes root.* "The Big Lie."

Where did Frank get the six hundred thousand figure? Oddly, it was the number of people Moses had taken from Egypt to the Promised Land, a mass escape from bondage that led to freedom for a mixed multitude.

Atomic Bombs/Nuclear Weapons

The atomic bomb was a revolutionary type of weapon with previously unseen destructive capability. World War II saw the development of increasingly aggressive weaponry, and the advent of nuclear weapons heralded an era in which nearly instantaneous mass destruction was possible and the risk that humankind could cause its own extinction became a real threat. Along with the invention of such powerful weapons came moral questions regarding if and when their use, resulting in extreme loss of human life, was justified. When the United States dropped two atomic bombs on Japan to end the war in the Pacific, a dangerous new standard had been set, and many countries invested in nuclear weapon programs.

The discovery of the weapon potential of nuclear reactions was first credited to German scientists Otto Han and Fritz Strassman, who both accidentally discovered the secret to splitting uranium atoms in 1938. Even though they had successfully split the uranium atom, the process of creating nuclear weapons was a long journey from there. During this time, Jewish scientists in Germany began to flee to the United States to escape the Nazi threat. Many scientists had feared that Germany would produce nuclear weapons, and so they warned the authorities in the United States. Albert Einstein and the physicist Leo Szilard wrote a letter about this to President Roosevelt, explaining that Germany could cause mass destruction if it built nuclear weapons and urged him to have the United States develop them. Roosevelt agreed to do research and development. This was kept top secret, and the work was named "the Manhattan Project."

Colonel Leslie R. Groves oversaw the Manhattan Project, which took many attempts to unravel the true

potential of nuclear bombs. In 1942, plutonium was created by the chemist Glenn Seaborg. This new material had greater nuclear power than other elements and was much easier to manufacture. Much of the development process went into designing the bomb and determining the amount of power it would release.

Although the United States had begun the process of creating an atomic bomb, several other countries had similar goals. Despite Germany being the first to split the uranium atom, it got sidetracked and was not able to complete nuclear arms first. Japan also made little progress.

The first U.S. nuclear test, named "Trinity," occurred in Los Alamos, New Mexico, on July 16, 1945, in an unoccupied, open field. When the Trinity test was performed on a steel tower, there was an abundance of heat, an immense mushroom cloud that surrounded the area, and the release of explosive energy that erased the tower. The test was a success, and the nuclear age was born, supported by the likes of famous scientists and mathematicians such as Albert Einstein, Enrico Fermi, and Richard Feynman. After the success of the Trinity bomb, more research went into enhancing and refining it.

For the Allies, the scenario of the Axis using nuclear weaponry would lead to destruction and downfall. On April 12, 1945, Harry Truman became the president of the United States as tensions between the Allies and Axis powers increased. On August 6, 1945, President Truman announced the attack on Hiroshima, revealing the Manhattan Project to the public. As the news spread, people had mixed emotions about the use of nuclear weapons—there was opposition, and there was support. Some said that triggering the bomb was inhumane, and that such a drastic action was ill supported. Others said that the bomb would end the war

sooner, fewer lives would be taken, and it could have averted an invasion. Protesters marched in the streets to express opposition.

The most significant turning point in the history of nuclear weapons was the dropping of the atomic bombs named “Little Boy” and “Fat Man.” “Little Boy” had dropped on Hiroshima on August 6, 1945, causing mass destruction and the loss of many lives, including the annihilation of the city. The second bomb, named “Fat Man,” was much more powerful and was dropped on Nagasaki on August 9, 1945, causing the immediate death of around 40,000 to 70,000 people. On August 10, 1945, after these bombings, Japan surrendered, signaling an end to World War II.

While many celebrated the end of a long war, others had mixed feelings about the victory, posing questions regarding the ethics and morals that had been pushed aside during the war.

The development and use of atomic bombs in World War II had introduced a new standard in the way wars were fought. As the United States was the first to test and use the atomic bomb, other countries are now faced with the pressure to create such weapons to meet the standard. Atomic bombs and their impact have become one of the most significant shifters of history. For the first time, the thought had been introduced that a single country could hold the power to annihilate another as well as to end a war. Nuclear weapons had revealed the immense power that we could wield. Although the atomic bomb was used as a solution by President Truman for ending World War II, the aftermath and effects of executing such power and destruction led to a new era of more countries mass-producing nuclear weapons as a means of both protection and threat.

Avenger Field

Avenger Field is located in Sweetwater, Texas, and was the home of the Women Airforce Service Pilots (WASPs) of World War II. The WASP flight school opened at Avenger Field on February 21, 1943, and was the first all-women military flight-training facility. The school closed on December 7, 1944.

The War Department had considered using female pilots as early as the 1930s, but despite the efforts of pioneer aviators Jacqueline Cochran (1906–1980) and Nancy Harkness Love (1914–1976) to promote the use of women pilots in an emergency role, women were not allowed to fly for the military until 1942.

In 1938, the U.S. government established the Civilian Pilot Training Program (CPTP) to train pilots in anticipation of military conflict. Twenty thousand civilian pilots were to be trained each year to provide a pool of candidates for the armed forces. The CPTP allowed women to train but limited the number of female pilot trainees to 1 woman for every 10 men.

The Women’s Auxiliary Ferrying Squadron (WAFS) was established in September 1942 and placed under the leadership of Love, who by this time had logged more than 1,200 hours of flying time and had a commercial pilot’s license. Love sent out telegrams to 83 women who had more than 500 hours of flight time. From that group, she recruited 27 experienced pilots to serve in the Ferry Command in a civilian capacity. These women, along with Love, became known as “the Originals.”

The WAFS pilots ferried aircraft from the factories to airfields and were initially limited to flying light aircraft and training vehicles, although they later flew larger planes, such as the P-51 Mustang, a long-range fighter plane, and the B-25 Mitchell bomber. The WAFS contribution to the war effort released male pilots for active duty, but at only 28 pilots the organization was too small to be very effective.

In 1942, General Hap Arnold (1886–1950) authorized the establishment of a women’s pilot-training program, the 319th Army Air Forces Flying Training Detachment (Women), better known as the Women’s Flying Training Detachment (WFTD). Cochran was appointed as director. Air Transport Command (ATC) created a 23-week pilot training course at Houston

Municipal Airport in Houston, Texas, for the women. The first class began in November 1942 as part of the 319th Army Air Force Women's Flying Training Detachment (AAFWFTD). Twenty-three women pilots graduated on April 24, 1943. They were instructed in basic flight training, cross-country navigation, and safety but received no combat training.

The WAFS and WFTD merged in 1943 to become the WASP. In February 1943, while the second class was in progress, the WASP relocated to Avenger Field in Sweetwater, Texas, and its flight-training program was expanded to 30 weeks. Previously a municipal airport, Avenger Field was leased to the War Department and used as a training ground for Royal Air Force and American pilots. In April 1943, Avenger Field became an all-female base.

WASP classes started monthly, and a total of 18 classes graduated between 1943 and 1944. More than 25,000 women applied to the program, but only 1,074 graduated from training and became pilots. The WASP was a paramilitary organization, but the female trainees lived in barracks, wore uniforms, and engaged in military-style physical training.

These civil service female pilots were assigned to 120 air bases nationwide. Their duties ranged from serving as flight-training instructors and glider tow pilots to towing targets for gunnery practice and transporting cargo. The WASP delivered more than 12,000

aircraft nationwide and flew 78 types of airplanes, including the legendary B-29 bomber the *Enola Gay*. Some of the better pilots were allowed to work with jet- and rocket-propelled planes and radar-controlled targets.

On September 30, 1943, the first bill was introduced in Congress that would have given the WASP full military status. The bill met with political resistance, as did further efforts to militarize the organization, and the WASP was ordered to disband by December 20, 1944. Avenger Field's flight school trained 232 women before ceasing operations in 1944.

Primary Document: Letters of Mary Anna Martin Wyll, a Pilot Trainee at Avenger Airfield (1944)

The Women Airforce Service Pilots (WASPs) trained at Avenger Field during 1943 to 1944. Eighteen classes of female pilots trained there. The following are several letters from one of those pilot trainees, Mary Anna Martin Wyll.

Letters from Avenger Field, 318th AAFSTD [Army Air Forces Flying Training Department], May 1944–December 1944.

Dearest Mother & Dad:

Gee, what a long day this has been. We came out in 2 huge semi-trailer trucks with benches arranged

in the trailer, and have spent the entire afternoon marching here and there and in lengthy lectures from the chief of staff, the primary training (flying) officer, the flight surgeon and the physical training teacher. So far, I'm thrilled beyond measure.

Got a glimpse of the flight line when we went down to the hangers to get our flying "zoot-suits" (Army fatigues) and other flying equipment.

18:00

Just got back from getting the rest of our uniforms. The stuff has cost me only \$15. This is everything I believe.

Betty Phillips met me at the hotel and has been over quite a few times today.

Taps—

Dearest Mother, Dad, Louise, Grandma and Berne Dean:

Well I've certainly had a taste of Army life. It's really rugged. We hardly have time to see the inside of our bays—Even our evenings are full of meetings and lectures.

We go on the flight line every day and I get thrilled about flying each time. Today they closed the PT flying during my period, hence, I didn't get to fly. Mr. Bingham talked to us students (5) for about 1 1/2 hours which was just as helpful as actually flying. The wind velocity gets very high here, that's why we didn't fly today.

I eat sand here all the time, but that's 100% better than battling with hot weather and insects. (I even like the snakes down here).

The other day I saw my first black widow spider. There are quite a few around here.

We had a fire drill last nite. It was quite complete. The fire engines even came around and hooked up the hose—just to wash the sidewalks which [sic] we stood out in the field in formation freezing to death.

You've never seen such whiz kids as we are in our bay. This morning we were up at 6:00, cleaned up the bay, made our beds, dressed and were in formation for breakfast at 6:25. At seven were sitting in class. Ground school was over at 10:00. 10:15 we went to drill. Then we were free to read our mail from 11:45–12:00. We changed our clothes and reported for the flight line at 1:30. At 7:00 left the flight line and ate dinner at 7:30. After dinner we thought well, we can rest until morning, but the officer of the day announced "There will be a meeting of all trainees at 21:00". This is my day!! For the life of me I can't see where I've had the chance to gain 5 lbs. (I weigh 118 now).

Maybe Saturday I'll have a chance to mail my laundry bag back home.

Goodnight and love,
Mary Anna

Thursday, June 15

Dearest Dad:

Happy Dad's day! I've got some good news for you. I hope it will compensate for flowers or somepin.'[sic] I soloed yesterday. It was a wonderful feeling and made Mr. Bingham quite happy. Today I soloed again which makes my total solo time 20 minutes and total dual 9 hrs and 56 minutes. We have been really hep on flying this week. The instructors are all anxious to get his students soloed. Mr. Bingham's five were all soloed by today. It's a grand old feeling to be up there alone.

The most thrilling thing just happened a few minutes ago. Three B-17's (Flying Fortresses) buzzed the field in formation and then peeled off to land one at a time. A jeep rushed out to the planes and took the pilots to the O.D. [Officer of the Day] office. By that time everyone had rushed to the flight line to get the deal. Guess why they came. To pick up the girls from W-5 for a dance tonight. The girls in the graduating class were guests of honors. Wouldn't that be wonderful to go to a dance about 100 miles away in a B-17. I hope that happens to W-10 around in December.

I'll let you in on a little military secret (supposedly). Miss Cochran was here this week. She ate in the dining room with W-10 this noon. She's very charming and makes you at home.

Dad—I hope you have a happy Dad's Day. I'll be thinking of you. Last Sun. it was Louise now it's Daddy.

Love

Mary Anna

B-17 Flying Fortress

The Boeing B-17 Flying Fortress was created in the 1930s to help aid the U.S. Army Air Corps (USAAC) during the strategic bombing of World War II. It was first known simply as Model 299. It did not gain its

"Flying Fortress" moniker until *Seattle Times* reporter Richard Smith called it that due to its many machine-gun mounts. Soon after, Boeing trademarked the name.

The Boeing B-17 Flying Fortress was the first modern bomber, created when the army requested a multiengine bomber. The prototype took less than 12

months to develop from the design board to the flight test. In the end, the plane contained four engines, a flight deck, and contained bombs along with five mounted .30-caliber machine guns.

The first B-17 went to war in 1941; however, as the war intensified, more armor and weapons were needed. This led to the next generation of B-17, called the B-17E, the first mass-produced model of the Flying Fortress. This model differed from the prototype in that it had more machine guns—nine—and a greater weight of bomb load at 4,000 pounds. Each version of the Boeing B-17 Flying Fortress became more heavily armed.

The next B-17 model created was the B-17G in 1943. The B-17G still had four engines; however, the gun count increased to 13 and the bomb load to 6,000 pounds. Wright Aeronautical licensed Studebaker to create the engines in the Boeing B-17 Flying Fortress. The B-17 contains the Wright R-1820 Cyclone 9 engine. It produced about 1,200 horsepower with a maximum speed of 287 miles per hour. Along with that, the B-17 was 74 feet 9 inches long with a wingspan of 103 feet 9 inches. It had a cruising speed of 150 miles per hour and could fly up to 3,750 miles. The B-17 was able to hold a crew of 10, which included two pilots, a bombardier, a navigator, a radio operator, and five gunners.

By May 1945, before the end of production, 12,726 B-17s had been produced. Of that total, 8,680 were the recent G model. The B-17 continued to be used until the end of the war, until the Boeing B-29 “Superfortress” was created and replaced the B-17. As of 2015, only 13 B-17s were still in operation but were featured at museums or air shows. The majority of B-17 planes were scrapped at the end of the war.

Big Science

“Big science” is a term used to describe the scientific research done during and after World War II. Big science encompassed the research that went into the scientific disciplines of physics, astronomy, and, later on, biology. Large-scale projects were conducted by groups of scientists and technicians, funded by the government. Big science differs from “small science,” which involves individuals or small groups creating a theoretical result. Projects such as the Hubble Space Telescope and the Apollo Program are examples of some well-known “big science” projects.

Before big science, science focused on creating basics or a platform for further research. For example, in the early 1800s, the goal of the chemist was to isolate and describe elementary substances and their properties as well as compounds of chemically active radicals of elements. It wasn’t until the late 1860s that the periodic table of elements was mapped. As for physicists, they focused on the study of mechanics, optics, and acoustics. It was not until the mid-19 century that physicists began doing experiments. By the end of the 19th century, many physical and chemical laboratories resembled factories with their output. While World War I did not affect everyday science, World War II dramatically changed the scope of the discipline.

The term “big science” became popular in 1961, as first mentioned in the article “Impact of Large-Scale Science on the United States” published in *Science* by Alvin M. Weinberg. He wrote it in response to Dwight D. Eisenhower’s farewell address, in which he warned of the danger of the “military-industrial complex.” Also at this time, the U.S. government was sponsoring big projects such as the Manhattan Project (the American atomic bomb program) and the Radiation Laboratory. In Weinberg’s article, he criticized how the then-current era of big science might negatively affect science in general, while expressing a sadness for the disappearance of small science.

Weinberg asked three specific questions: First, was big science ruining science? He stated that space research was not worth the money; he considered the effort wasted. Also, he believed that when too much money goes into a certain field, it becomes more focused on money than actual research, which makes the discipline “fat and lazy.” Second, was big science

ruining scientists financially? He stated that during the era, 10 percent of the federal budget, about 1.6 percent of the gross national product then, went to the funding of science. He explained that unless something could be done, within 65 years, all funds would focus on science and technology to the detriment of other areas of study. Last, he asked if scientists should divert more effort toward issues that bore more directly on human well-being than on such big-science spectacles as manned space travel and high-energy physics. Weinberg felt that we should not allow ourselves to be diverted from creating better human lives. In the end, he encouraged his colleagues to limit big science to the national laboratory system to prevent it from emerging in the universal system.

Still, many scientists began to study big science both in and out of a laboratory. Just a few years after Weinberg's article, Derek J. de Solla Price published *Little Science, Big Science* in 1963. It described how small science had given way to big science, describing the differences between them. Price is also known for laying the foundation of "scientometrics," which is the "science of science."

Although big science became popular during and after World War II, many questioned its validity against that of small science. Many did not like the idea that funds earmarked for smaller projects were being given to bigger projects. Also, due to the size of such research, big projects were given longer timelines than smaller projects, sometimes a decade or more. Many questioned whether big science projects were worth the price.

In this current era, a new term has been created to describe the type of science being done. "New big science" is large-scale research done at laboratories that is more focused on material science than, for example, astronomical research. Instead of exploring nuclear and subnuclear length scales, research in materials focuses on phenomena at atomic, molecular, and larger scales. Old and new big science differ in that old big science focused on the gradual increase of high-energy physics projects, increasing instrument size, collaboration, and experiment duration, while in new big science, there is no increase in instrument or collaboration size. The research ecosystem has simply grown and become more complicated. In new big science, scientists are involved in more fields, have access

to a more diverse instrument catalog, and have a faster turnover of research groups.

Blood Transfusion

Blood transfusions are very common in America to help boost low blood levels caused by surgery, injury, or diseases. The idea of using a blood transfusion to save a patient first came from William Harvey (1578–1657), an English physician who studied medicine in Padua, Italy, after graduating from Cambridge University in England. Harvey was the first person to understand the circulation of blood and publish his idea in *De Motu Cordis* in 1628. This led to an interest in transferring blood between animals, between humans, and between humans and animals.

The first successful blood transfusion occurred in 1665 in England. Richard Lower, a physician, conducted an experiment in which he transferred blood from one dog to another. This was considered a success when the dog survived. A couple of years later, in November 1667, Lower and another English physician, Edmund King, and Jean-Baptiste Den of France,

conducted separate experiments in blood transfusion involving an animal and a human. One experiment transferred blood from a sheep into the body of a human, and it was successful.

It was not until 1818 that the first blood transfusion from human to human occurred. James Blundell, a British obstetrician, was the first to do this as a treatment for postpartum hemorrhage. He concluded that only human blood should be transferred after observing that dogs given human blood always died. This led to a rise in blood transfusions from person to person.

It wasn't until 1901 that the first three human blood groups were discovered by an Austrian physician, Karl Landsteiner. This led to the idea of transferring blood by matching donors, which Ludvig Hektoen conceived and Reuben Ottenberg performed. Today, we classify blood types as A, B, AB, and O.

In the 1940s, the United States developed a national blood collection program. In 1941, the Red Cross established the National Blood Donor Service to collect blood for the U.S. military, with Dr. Charles R. Drew as medical director. This service was used to help injured soldiers during the Pearl Harbor attack. Controversy arose when Drew, a prominent African American medical doctor, protested the practice of racial segregation in the donation of blood, largely because it lacked a scientific foundation. When the American Red Cross maintained its policy of separating donated blood based on race, Drew resigned.

Nowadays, donated blood is used for direct blood transfusion. The process involves pumping blood and into a patient's blood vessel through an intravenous (IV) line and needle. The procedure takes one to four hours, depending on how much blood is being received. The patient is closely watched for the first 15 minutes to ensure there is no allergic reaction.

Bradberry, Henrietta (1903–1979)

An African American Chicago housewife and relatively unknown inventor, Henrietta Bradberry, created a collapsible bed rack and method of discharging waterproof torpedoes. Though her first invention, the bed rack for clothes, was relatively forgettable, her second invention, the device for discharging torpedoes underwater, was an important creation that helped the Allies in World War II. Despite the importance of her invention to the war effort, Henrietta Bradberry was largely lost to history, and she remains largely unknown. Although unsung, Bradberry's ingenuity as an inventor, and particularly as an African American woman inventor in this field, cannot be overstated.

Not much is known about Bradberry. She was born in 1903 in Franklin, Kentucky. After she married William Bradberry, they moved to Chicago, Illinois, where she created her two inventions and filed for their patents. She only graduated high school, but this did not deter her from inventing. In an interview, Bradberry explained that the ideas for her inventions came to her as she did chores. Bradberry used her free time to improve her inventions to the satisfaction of the Patent Office.

In 1943, she was awarded the patent on her collapsible bed rack, which she had filed for in 1941. The bed rack was attached at the foot of the bed to hang and refresh lightly worn clothes in the air. Clothes were hung on rods to let them dry out and so that fresh air circulated, alleviating odor in the days before washing machines were commonplace. The rack was collapsible with a pedal that raised and lowered it. Though not a very complex or revolutionary invention, it proved to be Bradberry's entry to the patent world.

Two years later, Bradberry filed for a patent for her pneumatically operated device that fired torpedoes underwater. In 1945, during World War II, she was awarded the patent. The complex device was operated pneumatically (with air or gas under pressure) and could fire multiple underwater torpedoes from submarines and subterranean stations. The device had three gears, allowing the operator to discharge more torpedoes than the previous standard of just one. The device prevented water from coming into contact with and damaging the inner mechanisms that discharged the torpedoes.

Bradberry attempted numerous times, with the support of her patent attorney, to find willing manufacturers or buyers to buy out the patent rights. However, these aspirations never came to fruition. This may have been due to her lack of experience in inventing or to superficial reasons such as her race and gender. Disenchanted by repeated failures to gain from her hard-earned efforts, Bradberry never filed for other patents. She died on May 17, 1979, in Chicago.

Calutron Girls

The Calutron Girls were a group of young women who monitored dials for the Oak Ridge National Laboratory's spectrometer, or "calutron," that made the enriched uranium for the Manhattan Project for use in the first atomic bombs.

Calutrons used giant electromagnets to separate uranium-235 from uranium-238. The original calutron was developed at the University of California, Berkeley, but once the machine was fully operational, the university turned it over to the Tennessee Eastman Company, who hired young women to work in the calutron facility. None of these women had more than

Evelyn Babb, one of the original "calutron girls," hired by the U.S. government to work on the Manhattan Project at the nuclear weapons plant in Oak Ridge, Tennessee, died in 2015 at the age of 90. Just out of high school, Babb and other young women like her monitored the calutron, the machine that separated enriched uranium isotopes. (Ali Rizvi/McClatchy DC/TNS via Getty Images)

a high school education; nor did they know anything about the uranium separation or its eventual use in atomic bombs.

The women were trained to operate the laboratory machines but not told what the machines did. They lived in dormitories near the lab, for which they were charged \$10 a month. The women worked seven days a week in rotating shifts and were not allowed to speak to each other while they worked. In a contest between Berkeley scientists and the so-called hillbilly girls in Tennessee, the calutron girls outproduced their educated, male colleagues. Uranium enriched at the Tennessee labs was shipped to Los Alamos, New Mexico, for use in atomic bomb building.

Clarke, Edith (1883–1959)

Edith Clarke graduated from the Massachusetts Institute of Technology (MIT) in 1919 to become the first female electrical engineer in the United States. Unable to find work, she invented the Clarke Calculator and taught physics in Turkey before returning to the United States to work as an engineer for General Electric (GE). She became the first female engineering professor when the University of Texas at Austin hired her in 1947.

Born in 1883 to Susan Dorsey Owings and John R. Clarke, Edith was one of nine children. Her parents died when she was 12, after which her older sister raised her. She used money left to her at her parents' death to attend Vassar College, where she studied math and astronomy. She graduated in 1908 and took a job teaching at Marshall College, a private women's school, in San Francisco. She left San Francisco to

study civil engineering at the University of Wisconsin-Madison. In 1912, she got a job as a "computer" for American Telephone and Telegraph (AT&T). In 1918, she enrolled in MIT and a year later earned a master's degree in electrical engineering.

Having earned her master's, Clarke looked for an engineering job. She could find no one who would hire a woman as an engineer, so she took a job supervising the female "calculators" who did the math in GE's Turbine Engineering Department. In 1921, she filed for a patent for the Clarke Calculator, an early graphing calculator that solved current and voltage equations. Soon after, she left for the Constantinople Women's College, which had offered her a job. She taught in Turkey for two years before returning to the United States to take a job with General Electric in the engineering department. In 1926, she delivered a paper to the American Institute of Electrical Engineers (AIEE). She was the first woman to do so. The paper, which posited hyperbolic functions for calculating maximum electrical line power, won the Best National Paper Prize from the AIEE in 1941.

In 1943, while still working for GE, she wrote and published *Circuit Analysis of AC Power Systems*, a textbook based on lectures she gave to GE engineers. She published a second edition of the volume in 1950. Clarke retired from GE in 1945. Two years later, the University of Texas at Austin hired her as a professor in their Electrical Engineering department. She was the first female ever to be hired as an electrical engineering professor, as well as the first woman inducted into the AIEE as a fellow. She died in 1959. In 2015, the National Inventors Hall of Fame inducted her into their ranks.

Curtiss-Wright Aeronautical Engineering Cadettes

The Curtiss-Wright Aeronautical Engineering Cadettes was a cadre of young women who met a critical need for aeronautical engineers during World War II from 1943 to 1945. Unlike Rosie the Riveter and Wanda the Welder, the cadettes were the first university-trained female aeronautical engineers in the United States. In 10 months or less, the cadettes completed three years of graduate engineering course work. They were immediately employed in the development of the Curtiss-Wright SB2C Helldiver Bomber. In addition to bailing out an aviation company whose planes were vital to winning World War II, the cadettes' efforts proved that women were capable of excelling in the male-dominated field of aeronautical engineering.

The Curtiss-Wright Engineering Cadette program formed when aviation giant Curtiss-Wright was struggling with the engineering revisions required to improve its SB2C Helldiver Bomber. To meet the wartime shortage of male engineers, Curtiss-Wright partnered with seven universities to prepare female college students for a career in aeronautical engineering. Participants in the 1943 cadette class had to be 18 years of age and had to have completed one year of college and scored in the top third of their mathematics classes. The intensive course compressed two to three years of graduate engineering course work into 44 weeks. To avoid distractions from their family and friends, the young women were required to travel to a distant university. In addition to opening the door to engineering faculty and a career in aeronautical engineering with Curtiss-Wright, the program covered all expenses related to tuition, room and board, and travel. Also, as Curtiss-Wright employees, each cadette earned \$10 a week, then fairly good wages for a woman.

The cadettes' course load included advanced mathematics, applied geometry, drafting, flight theory and aerodynamics, aircraft materials, and stress analysis. Courses moved so quickly that cadettes joked that if one dropped a pencil and bent to pick it up, she would miss an entire course in algebra. In spite of the rapid pace, the program could not keep up with the demand for engineers. By 1945, the cadette program

was open to high school juniors and seniors, and the curriculum was further compressed, covering three years of content in six months. The cadette curriculum ran ahead by one year to prevent the girls from distracting the male students by asking for help. At final exam time, the cadettes outperformed the men. The top three scores went to female cadettes.

Of the 918 graduating cadettes, 365 were assigned to the Columbus, Ohio, plant and walked into an ongoing design nightmare. The U.S. Navy had commissioned a carrier-based, large-capacity dive-bombing aircraft called the SB2C (Scout Bomber Second Series Curtiss, or Helldiver), which defied basic principles of aeronautical design. Rather than being slim and streamlined, the fuselage (body) of the plane was short and wide with a large, heavy tail. To meet the parking requirement, the Helldiver's wings folded up to form a triangle over the body. Pilots found the massive plane hard to control, so they decided that "SB2C" meant "Son of a Bitch, Second Class." Others simply called the plane the "Big-Tailed Beast." Over four years, 889 design revisions would be required to address all of its problems. The cadettes were to translate the revised specifications into detailed, accurate production drawings, check the plans for accuracy, and inspect the planes on the production lines. Although their official title was "assistant engineer," the cadettes rarely saw a senior engineer on the production floor. In some cases, a 17-year-old cadette would be supervising the work of adult riveters and welders.

In spite of Curtiss-Wright's promises, the end of the war brought the end of the Curtiss-Wright Aeronautical Engineering Cadettes. On August 15, 1945, the radio pink slip arrived when newscasters in Columbus, Ohio, announced that the war was over and that Curtiss-Wright cadettes need not report to work. A few cadettes returned to Curtiss-Wright briefly to train the returning servicemen to take over their jobs. Federal legislation to support returning soldiers effectively shut women out of professional positions and the opportunity to study engineering. The majority of the cadettes started new careers as teachers and homemakers. The women who designed the planes that won the war became unsung heroines of the Greatest Generation.

D Rations

D Rations, or military chocolate bars, were introduced during World War II to fulfill the need for an emergency energy source included in ration supplies for soldiers. The government commissioned the Hershey Company (known at the time as Hershey Foods Corporation) to create the product, which had to be high in energy content, weigh four ounces, withstand much more heat than normal chocolate so as to not melt on the field, and not taste exceptional—so as to dissuade the soldiers from eating the chocolate before necessary.

Army quartermaster Col. Paul Logan approached Hershey in 1937, and the bars, originally called “Logan bars,” were experimentally shipped out to be used in the Philippines, Texas, and Panama. From then on, the United States ordered the bars for soldiers in World War II, where they were universally viewed as having an unappealing and bitter taste and an overly chewy texture. Hershey Foods received the Army-Navy Production Excellence Award in 1942 for its involvement in the war effort, an honor given to only approximately 4,000 companies out of nearly 85,000 involved.

Electric Guitar

The electric guitar was developed to increase the volume of a guitar, which could not be heard above other instruments in jazz or swing bands. Originally, electric guitars were relegated to the rhythm sections of bands, but the advent of rock 'n' roll music made the electric guitar the preeminent instrument in modern popular music.

Early attempts to increase the volume of acoustic guitars led to the use of steel strings, bigger instruments, and the use of microphones connected to loudspeakers, which produced feedback. Lloyd Loar of Gibson mounted an electrostatic pickup on various archtop guitars around 1923, but Gibson was not yet interested in manufacturing electric instruments.

The Dopyera brothers built metal-bodied resonator guitars under the National and Dobro names, with metal discs mounted under the bridge to act like mechanical loudspeakers. Stromberg-Voisinet advertised an “Electro” with a magnetic pickup in 1928, but there is no evidence that it was ever manufactured. Historians therefore credit the Rickenbacker A-22 “frying pan” as the first electric guitar. Because of the popularity of Hawaiian music, which utilized lap-steel guitars, Adolph Rickenbacker, George Beauchamp, and Paul Barth formed the Ro-Pat-In Corporation to make electric guitars. Their aluminum-bodied lap-steel guitars, with magnetic horseshoe pickups designed by Beauchamp, came out in 1932 and were nicknamed “frying pans” due to their long-handled shape. The company was eventually renamed Rickenbacker.

Hawaiian guitars were played while resting on the player's lap; the player slid a bar along the neck, unlike with traditional, “Spanish-style” guitars. Gibson introduced the ES-150 (“ES” for “Electric Spanish”) in 1936, and other companies began making electric instruments as well. Electric Spanish-style guitars were hollow-bodied (acoustic) instruments to which magnetic pickups were added.

The two performers who helped popularize the electric guitar were Les Paul, who used an electrified Gibson L-50 archtop on the radio with Fred Waring's Pennsylvanians, and Charlie Christian, who played both a Gibson ES-150 and ES-250 with the Benny

Goodman band. Christian was enormously popular during his short life and, due to his recordings with Goodman, showed that the electric guitar could produce single-line solos like a saxophone or trumpet, transforming it from a rhythm to a solo instrument. Christian, who died of tuberculosis in 1942 at age 25, was so influential that Gibson's bar pickup is still called the "Charlie Christian pickup."

Vibrations from hollow-body guitars, however, interfered with vibrations from the strings, producing feedback and distortion, leading several designers to experiment with solid-body guitars. Les Paul designed "the Log" in the early 1940s, which was a solid block of wood with two pickups. Merle Travis commissioned a solid-body guitar from Paul Bigsby in 1947.

Leo Fender, who owned a radio repair shop, partnered with George Fullerton and was the first to successfully mass-produce solid-body guitars. Originally released as the Esquire with only one pickup, the Fender Broadcaster came out in 1950 and was made of a solid plank of ash with rounded corners, a single cutaway, two pickups, and a maple neck that was bolted to the body. Due to a trademark complaint, its name was changed to the Telecaster in 1951. It became extremely popular with country and western bands because of its twangy sound, and unlike electrified acoustic instruments, it had to be amplified to be heard. Conveniently, Fender also manufactured an amplifier. Fender had further success with the first electric bass guitar in 1951, followed by the Stratocaster guitar in 1954, which had two cutaways, three pickups, a tremolo bar, and a contoured body. It was quickly adopted by rock 'n' roll musicians, notably Buddy Holly.

Although Gibson resisted solid-body guitars for fear that they would tarnish its reputation for quality archtop models, the success of the Fender Telecaster prompted it to design a solid-body model that it brought to Les Paul for his endorsement. The Gibson Les Paul was issued in 1952 and had a two-piece, archtop body made of maple and mahogany, and two pickups. It later included "humbucker" pickups, a double-coil device that canceled hum.

Fermi, Enrico (1901–1954)

Italian American physicist Enrico Fermi is considered one of the principle nuclear-age scientists. He immigrated to the United States in 1939, the year after he received the Nobel Prize, fleeing Italian racial laws that negatively affected his Jewish wife.

Enrico Fermi was born in 1901 in Rome, Italy, to Ida de Gattis and Alberto Fermi. He went to college in Pisa, where he initially studied mathematics but switched to physics in 1920. His first two papers explored issues in relativity, the first connecting mass and movement and the second proving that electrical charge has weight. He earned his doctorate when he was 20 years old, after which he spent a semester studying with Max Born at the University of Göttingen. In 1924, he won a Rockefeller fellowship and studied with Paul Ehrenfest in Leiden. All the while, he, along with Einstein and others, was inventing the field of theoretical physics. In 1925, Fermi wrote a paper in which he posited a principle for particles later called "Fermions" and "bosons." Fermi would later postulate the existence of neutrinos, though they would not be discovered until after his death.

In 1926, he became a professor at the Sapienza University in Rome. His mentor in Rome, Orso Mario Corbino, was a member of Italian dictator Benito Mussolini's cabinet. Two years later, Fermi published a textbook in particle physics that gained him university sufficient fame that Sapienza became an important physics school.

In 1938, Fermi won the Nobel Prize in Physics for his discoveries in neutron irradiation and nuclear reactions. He went to Stockholm to receive his prize and from there went to the United States, fleeing the racist and anti-Semitic racial laws enacted in Italy and Germany. He took a job at Columbia University

and, while working with nuclear physicists, learned of recent advances in nuclear fission theory. Fermi joined a team of Columbia scientists including Eugene Booth, John Dunning, Herbert Anderson, Francis Slack, and Norris Glasoe in efforts to measure energy release from neutron-bombarded uranium. Fermi thought that fission could be achieved with blocks of uranium oxide if they used graphite, rather than water, to better encourage self-sustaining nuclear reactions. Fermi published the results of this work and in 1939 gave a lecture on it to scientists at the U.S. Navy. Not long after Albert Einstein (1879–1955) and other scientists sent President Franklin Roosevelt (1882–1945) a letter warning that Nazi Germany was surely working on a nuclear bomb and that the United States would be best served by developing that weapon first.

Thus, the impetus for the Manhattan Project at Los Alamos, New Mexico, was born. While others put together the New Mexico nuclear facility, Fermi and a team of scientists and engineers built a self-sustaining nuclear reactor at a facility outside Chicago in 1942. Fermi moved his research and family to Los Alamos in mid-1944, where director Robert Oppenheimer (1904–1967) made him associate director. Fermi took part in the research that culminated in a successful test of a nuclear bomb in July 1945 known as the Trinity Test. Fermi would measure the bomb site after the blast and calculate a 10-kiloton explosion. In reality, the explosion was almost twice that powerful at 18.6 kilotons.

Fermi next joined a committee to determine where the nuclear bomb might next be detonated. The committee agreed that the bomb should not be used without warning, but military authorities ignored the committee and dropped two bombs, one on Hiroshima, Japan, and the other on Nagasaki, Japan, on August 6 and 9 respectively. Fermi and the other Los Alamos physicists learned of the nuclear bombs the same way the rest of America did: from a radio announcement.

In July 1945, Fermi went to work for the University of Chicago, where he continued his work on nuclear reactions and theoretical physics. He mentored German American physicist Maria Goeppert-Mayer, who had also worked at Los Alamos and in

1963 won the Nobel Prize in Physics. Fermi died of stomach cancer in 1954. Today, he is considered one of the most influential physicists that ever lived. Indeed, though today Albert Einstein is far more famous, historians of science contend that Fermi's research, mentorship, and communication skills outstripped Einstein's. In 1956, the Atomic Energy Commission named its highest award after Enrico Fermi.

FM Radio

Edwin Howard Armstrong (1890–1954) received four patents in 1933 for the frequency modulation (FM) method of broadcasting radio signals. He had been working to reduce static, an inherent problem with amplitude modulation (AM) broadcasts. While AM modulates a radio wave's amplitude to carry a signal, FM changes the frequency of the wave, resulting in a stronger, cleaner signal. Armstrong demonstrated FM's superiority by broadcasting from the Empire State Building, but competition from AM stations and patent suits threatened the nascent FM industry. After World War II, the Federal Communications Commission (FCC) reassigned the FM band to a higher range of the broadcast spectrum, and many FM stations were forced off the air. FM Radio made a comeback in the late 20th century. The industry recovered slowly, but by the late 1970s, FM stations outnumbered AM

stations considerably. FM radio continues to dominate the modern radio industry.

Freeze-Dried Food

The process of freeze-drying food has ancient origins. As early as 1250 BC, the Incas of Peru stored food crops in the mountains in winter. The cold would freeze it, and the low air pressure at high altitudes caused its moisture to vaporize, slowly drying it. This made food last much longer.

This process was not well understood until the early 1900s, when scientists needed to develop techniques to preserve human and animal tissues without damaging them. They found that freezing the tissue and then applying a vacuum to it would quickly force its water out in vapor form, preserving it virtually intact. In the mid-1900s, the process was applied to foods for the same reason—freeze-drying preserves flavor and color.

Freeze-drying's scientific name is "lyophilization." It is derived from Greek and literally means "solvent-loving process," as the freeze-dried product will rapidly reabsorb the water (or solvent) that was removed when it is added back in. The first freeze-dried food to be made commercially available was instant coffee.

Garbage Disposal

Garbage disposals, also known as waste disposal units and "garburators," are electrically powered mechanisms installed between a sink drain and trap that are designed to shred or grind food into bits small enough to pass through household water pipes.

In 1927, Wisconsin architect John Hammes applied for the first garbage disposal patent. Hammes founded InSinkErator and began marketing his invention in 1940, five years after General Electric marketed its own garbage disposal unit.

The machine consists of a .5- to 1-horsepower motor that spins a circular table that runs the grinding chamber. Waste food enters the chamber and is ground by a sharp-edged cutting ring. Garbage disposal users

must run the water while the disposal unit is engaged so that it flushes the ground-up material down the pipes leading from the sink.

While the garbage disposal is a popular home mechanism, many cities prohibit their use on the grounds that they damage sewer systems. New York City had a longtime ban on garbage disposals for just this reason, until Environmental Protection Agency studies showed them to be safe. In 1997, New York City rescinded its prohibition against garbage disposals. Other cities followed soon after.

Gas Mask

The Great War was not great—and to soldiers on the front line, it was definitely hell. Add to the dangers of trench warfare and the fear of being shot the fear of a gas so toxic it killed within minutes. Without the invention of the gas mask, more lives would have been lost or people maimed from the effect of breathing poisonous gases such as chlorine or mustard.

A gas mask is a small respirator to aid in breathing. It must fit securely to the wearer's face, tightly enough that no fumes enter from any openings other than the breathing area. There are several variations. As the wearer breathes in, the air passes through a filter, purifying it before it reaches the wearer's lungs. Filters vary from pads that purify the air and keep smoke or dust particles out to activated charcoal filters that trap toxic gases and vapors.

Some gases are so toxic that they can burn skin through clothes. The gas mask can help with some of these, but not all.

Golden Gate Bridge

The tallest suspension bridge in the United States, the Golden Gate was once also the longest and tallest in the entire world. Spanning 4,200 feet, reaching a height of 746 feet and a length of 8,981 feet, the bridge became an icon of the city of San Francisco shortly after its opening in 1937.

Though Joseph Strauss conceived the idea and served as chief engineer of design and construction, he had yet to work on a suspension bridge, so other experts joined the team—among them Leon Moisseiff, Irving Morrow, and Charles Alton Ellis.

Construction began on January 5, 1933, and officially concluded four years later on opening day: May 27, 1937. The process had been anything but smooth, beginning with the funding of such an infrastructure project. Strauss personally sought help from Bank of America president Amadeo Giannini, who provided a crucial boost by agreeing to buy \$6 million in bonds in 1932.

As it was the first of its type of bridge to span such a distance, many new ideas were involved. Moisseiff created the “deflection theory” by which a thin, flexible roadway would flex in the wind, greatly reducing stress by transmitting forces via suspension cables to the bridge towers. Eventually, 250 pairs of vertical suspender ropes were attached to two main cables. The group also created the idea of designing a “bridge within a bridge” to avoid the need to demolish a nearby fort that had historic value stretching back before the Civil War.

Safety became an issue in such a large project, and Strauss invented a movable safety net that stretched beneath the changing areas of daily construction, prepared to catch any workers who fell from the bridge. In the end, 19 men were saved by the new contraption, though at one point, an entire scaffold broke and fell into the net, which tore it open; 10 of the 12 men on that scaffold died. Calculations by the engineers claimed the bridge could withstand winds to about 70

miles an hour and recommended that it be closed on days of higher speeds. To date, that has only happened three times.

Primary Document: Letter of Charles Ellis to the *San Francisco Chronicle* Regarding the Golden Gate Bridge (1930)

Though today the Golden Gate Bridge is widely considered one of the most beautiful bridges in the world and a true American icon, its construction was not without controversy. Chief engineer and designer Joseph Strauss employed Charles Ellis to do the principal engineering calculations for the bridge. Relations between the two men became strained when Ellis became convinced that the bridge's design was faulty. Strauss fired Ellis in November 1931. Strauss largely took credit for the bridge, though in 2007, the Golden Gate Bridge District formally gave Ellis credit for the bridge design. The following is an excerpt of a letter that Ellis wrote to the San Francisco Chronicle explaining his concerns.

March 11, 1930

Preliminary test borings completed. I left San Francisco for Chicago and started the preliminary design and estimate. I had many times tried to convince Mr. Strauss that a year would be necessary to do this work properly.

Plate girder, simple truss, arch and cantilever spans are very much alike in that they all perform their duties as a beam in resisting bending moments and shears. A suspension span is in a class by itself since it acts like a clothes line instead of a beam. Hence it is at once obvious that an engineer may be thoroughly familiar with all other types of bridges and yet be a novice in suspension span theory and design.

Such was the situation in our office. I could not turn over the computations to any one else but had to make them myself, and at the same time initiate one of our men, Mr. Clarahan, a former student of mine, into the fundamental theory. Mr. Strauss, however, insisted that the work must and could be done in three or four months, inasmuch as he would write the report in San Francisco while I was making the design and estimate in Chicago.

There was a large bascule bridge job going through the office at this time in charge of Mr. Paine on which a bonus was to be paid if completed on a given date and because of this, it was with much difficulty that I was able to arrange for the release of a few men to help me. By working twelve to fourteen hours a day I personally made all the computations and the entire design and with a few men at my command—at most six or eight at any one time—the plans were sufficiently laid out . . .

A meeting with the three consultants was held in Chicago to review the work. Mr. Strauss was also here. Three sessions were held on each of two days attended by the consultants and myself. During all these sessions except the last one when his report was discussed Mr. Strauss, the chief engineer, was not in the room once to sit down or take any part in the discussions. Subsequent to this meeting the plans were finished, tracings made and on August 22 I arrived in San Francisco with the preliminary plans completed. Mr. Strauss had meanwhile written his report in San Francisco so that it can be correctly stated that he knew as little about my plans as I knew about his report.

Some of the Directors who reviewed his report were not satisfied with it. I understand that the Directors cut out much of it and turned the remainder over to Mr. Taylor, the traffic engineer, to rewrite for publication. Several of the Directors and the General Manager asked me confidentially for my opinion of the report and my reply was that, since I was in Mr. Strauss' employ, I must decline to comment. Mr. Strauss, however, arrived at the erroneous conclusion that the dissatisfaction on the part of the Directors was traceable to me.

It was at this time that I first felt Mr. Strauss' displeasure. For years it had been thoroughly understood that I was to have charge of this work, and that

at the proper time we would transfer all the work to San Francisco where I would be located as Resident Engineer.

It was also understood that when the preliminary plans were delivered, I should remain in San Francisco and give technical advice during the bond campaign, but when he realized that the Directors were coming to me for information and advice he instructed me to return to Chicago at once.

November 4, 1930

Bonds voted. Mr. Strauss immediately sent for Mr. Paine who up to this time had had absolutely no connection whatever with the work or any other work of the suspension type. He was a former student of mine and was brought into the Strauss organization several years ago by me. He was in San Francisco about two weeks. Two days before his return to the office I received a letter from Mr. Strauss

which in effect took the work out of my hands and placed it in charge of Paine with no reasons or explanations whatever given for such a drastic action.

The only portion left in my charge related to the computations and specifications. This arrangement made an almost impossible situation since the computations, design, plans and specifications were all so closely interwoven that to separate them was simply inviting complications.

Probably the only reason the computations were left in my hands was because, with the exception of Clarahan who was just getting his initiation into this sort of work, I was the only man in the organization who had even the slightest conception of what the computations were all about.

Helicopter

A helicopter is a type of aircraft that uses lift and propulsion supplied by rotor blades that enable the aircraft to take off. Unlike fixed-wing aircraft, a helicopter can move in almost any direction with ease and hover in one place. The first operational helicopter took flight around 1936, but the helicopter itself was still under limited production until 1942. One of the first companies to build and sell these aircraft was Sikorsky Aircraft Corporation based out of Stratford, Connecticut. The founder was Igor Sikorsky, an aircraft engineer who had immigrated to the Americas from Ukraine.

Ivan Sikorsky was born in Kiev, Ukraine, in 1889 to Mariya and Ivan Sikorsky. Sikorsky immigrated to the United States in 1919, fleeing the Bolshevik revolution, and founded Sikorsky Helicopter Corporation in 1923. Composer Sergei Rachmaninoff gave Sikorsky \$5,000 to fund his new company. Sikorsky focused on developing more practical helicopters and succeeded in creating an extremely stable helicopter, the Vought-Sikorsky 300. It was the first of its kind, a single-rotor, fully controllable helicopter that would become the model for the vast majority of modern helicopters.

Sikorsky made helicopters for civilian and military use. The Sikorsky R-4 was one of the first helicopters to be mass-produced for military purposes. It employed a new closed cabin, meaning that the inside was completely enclosed; helicopters at the time did not have doors like cars do. This paved the way for modern helicopters, which vary in the number of rotors and number of doors, and, of course, they have improved stability/design.

Aircrafts use a lifting force to fly, using their wings and speed to create lift. However, helicopters use lift force a different way. The blades are their wings, and instead of using speed to take off, the machine uses its blades to move air around the body to create lift. This gives the helicopter some advantages. It does not need speed to create lift force, it has more mobility or freedom in the air, and it can even hover in a single spot while in flight. With these benefits, the helicopter has different practical uses as compared to airplanes. Helicopters are used by hospitals, to help fight fires, on rescue missions, by the military, by the police, and even by the media. Civilians can become licensed to fly helicopters. Companies use helicopters to fly executives short distances.

Military helicopters are used in a variety of ways. Foremost, the military helicopter is modified to be

armored, bulletproof, and outfitted with appropriate communications systems. The American military mainly uses helicopters in the transport of personnel. There are also helicopters made for offensive operations, particularly in anti-vehicle and support positions. They can even be used on reconnaissance missions to observe and gather information.

Helicopters also help civilians, and depending on the area, they have different uses. For example, helicopters can be used to fight fires by dropping off supplies for firefighters or dropping chemicals directly onto fires. They can even be used in rescue missions when a natural disaster occurs and there is no way through the destruction except by air. The most common disasters of this kind are hurricanes and rock- or mudslides. Helicopters are even used by the police force for tracking or just observation. The best example of this is when there is a car chase at night when patrol cars lose visibility. The police helicopter can keep a spotlight on the criminal as long as he or she is in the open, giving the on-the-ground police an opportunity to proceed more safely. The media uses helicopters as well, to cover both news stories and traffic conditions. The National Aeronautics and Space Administration (NASA) uses helicopters to conduct research. It studies crash simulations, the material used to make helicopters, aerodynamics, engine mechanics, and even carrying capacity.

Drones can also be considered a natural progression of helicopter technology. Drones use rotors to fly and hover, but they do so without on-board personnel. This shows how rotor aircraft design is changing in both design and application.

Igor Sikorsky remains a legendary pioneer in aviation technology. His first wife, Olga, chose to remain in Russia after the revolution, and the couple divorced. In 1923, Sikorsky's sister brought his daughter, Tania, to the United States. A year later, Elizabeth Semion married Sikorsky. They had four sons, the oldest of whom worked at Sikorsky Aircraft. Igor Sikorsky died in 1972.

Hoover Dam

The Hoover Dam, a massive concrete, arch-gravity dam located in the Black Canyon of the Colorado River on the border between Nevada and Arizona, has been regarded as an engineering marvel with both functional and awe-inspiring design. The government proposed to build the dam to prevent future floods and droughts, which had devastated the area. Once approved, the construction project (1931–1936) employed thousands of workers. The builders contributed hard work and ingenuity to insure the success of the project. Some workers lost their lives.

After the dam was completed, it formed a reservoir (Lake Mead) that insured the year-round availability of water for irrigation and domestic use to all states with water rights. In addition, the dam provided hydroelectric power to the region. In sum, the dam fulfilled the mission that legislators had originally proposed. In fact, the dam's success encouraged legislators to fund other large projects. The dam provided many benefits to the region. However, some environmentalists pointed out that there were costs associated with human tampering with the natural environment. In later years, construction projects failed to eclipse the importance of Hoover Dam as an important American technological achievement.

Especially in western American territories, in the late 1800s, drinking water was the most precious resource. Farmers and ranchers often fought over water rights. In addition, the natural occurrences of floods and droughts caused havoc on both agricultural and cattle enterprises. Long overdue, President

Theodore Roosevelt (1858–1919) signed the Bureau of Reclamation into law in 1902. The Bureau oversaw the sale of public lands in 16 states, and it used the money from the sales to fund various projects. The Bureau's main objective was irrigation (a controlled application of water through human-made systems).

The Keokuk Canal, which had been built in Iowa in 1877, was the first irrigation system to also house a hydroelectric plant on the Mississippi River by 1913. In fact, at that time, the Keokuk hydroelectric plant was the largest in the world. Plants of this type generated electricity by harnessing the flow of falling water to turn turbines. The Keokuk plant and other early plants like it most often used their small amount of electricity themselves. When an excess of electricity was produced, plants sold it and applied the revenue to their own ongoing projects. Sale of electricity on a large scale was not a priority, because it was not the primary purpose of these kinds of projects. However, as the scale of projects (and turbines) increased by the 1920s and 1930s, the sale of electricity to regions of the nation became possible.

Between 1905 and 1907, the Colorado River experienced major floods. The Bureau commissioned a U.S. geological survey of the area to determine an ideal place for a dam. After examining more than 70 sites along the river, the survey team recommended two possibilities: Boulder Canyon and Black Canyon. Other surveys were conducted during the next decade to determine which of these two locations was best, but nothing was built. In 1921, Secretary of Commerce Herbert Hoover (1874–1964) got the project moving again when he recommended that a dam for the Colorado River be built.

In 1924, another survey report stated that Black Canyon was the best spot to build the dam because of its bedrock depth, which would offer greater support. In 1928, the U.S. Congress authorized the Boulder Canyon Project Act for the construction of Boulder Dam in Black Canyon on the Nevada-Arizona line. After Hoover became president in 1929, he continued to support the project. Hoover's supporters made a couple of attempts (in 1929 and in 1930) to name the dam after Hoover, but the bills failed to secure congressional approval. Traditionally, projects were named after the law that made them possible.

According to the Boulder Canyon Project Act, "Boulder Dam" had three main purposes. First, it would provide human control over the river, which would allow engineers to prevent floods. It would also lead to a calmer river that would be much more navigable. Second, the dam would form a reservoir (Lake Mead) that would insure the year-round availability of water for irrigation and domestic use to all states with Colorado River water rights. Third, it would provide hydroelectric power to the region.

Construction on the dam began in 1931, two years after the start of the Great Depression (1929–1939). Many people were desperate for jobs, and, in spite of the dangerous working conditions, the project attracted many workers. In total, 96 workers died on the job, and dozens more died of job-related ailments. Six construction companies (Six Companies) merged to get the massive contract. Before work could begin, crews built Boulder City to house the workers. They also built highways and railroads from the dam site to Boulder City and Las Vegas, Nevada. Once the infrastructure was in place, work on the dam itself began.

First, they diverted the Colorado River through a series of small dams and dynamite-blasted tunnels. According to the plan, after the dam was completed and the river restored to its place, the empty tunnels would then be used to house the electric plant generators. In the meantime, workers dug out more than 382,300 cubic meters (500,000 cubic yards) of mud from the exposed river bed to expose the bedrock, which was located about 40 feet (12 meters) below the surface. While workers below prepared the foundation for the dam, other workers suspended from wires used dynamite to smooth out canyon walls to create a better joining surface with the dam.

Two years later, in 1933, workers began pouring concrete for the dam's base. The concrete pouring process took an additional two years, because workers had to allow time for it to dry properly. The rest of the dam was made up of columns filled with concrete. Engineers knew that concrete released heat when it cooled, and they were concerned that the massive amount of concrete might release so much heat that it might prevent the concrete from setting correctly, which would hurt the integrity of the dam. To compensate, engineers added a concrete cooling system. They

instructed workers to imbed 582 miles of one-inch-diameter pipes in the concrete wall. They then sent ice water through the pipes to cool the concrete as it dried. In total, they poured 230 blocks of concrete (a volume of 3.25 million cubic yards or 2.49 cubic meters).

When it was completed, the dam exceeded the masonry mass of the Great Pyramid of Giza, Egypt. It weighed 6,600,000 tons. According to another estimate, the concrete that was used to build the dam would have been enough to pave a 16-foot (4.9-meter)-wide highway from New York to San Francisco. The magnitude of engineering achievement and size of the project was comparable to the building of the Panama Canal earlier in the century.

In 1935, one year before the work was completed, President Franklin D. Roosevelt (1882–1945), stated the benefits of the dam at a dedication ceremony. Roosevelt sought to align the project with his New Deal agenda of government-run projects designed to help Americans during hardships. He stated that “Boulder Dam” had the ability to prevent floods, to provide irrigation for farmers, and to generate electricity to run factories and provide lighting to residential homes. Roosevelt opposed the idea of naming the dam after Hoover, whom he believed represented anti-New Deal sentiments. (In fact, it was not until two years after Roosevelt’s death that Congress formally adopted “Hoover Dam” as its formal name.) In his speech, Roosevelt wished to provide Americans with hope by pointing out that even during the hardships of the Great Depression, American ingenuity and hard work could accomplish great things.

During the last year of construction, the Colorado River was reverted to its original path and Lake Mead, one of the world’s largest man-made bodies of water, was filled. The reservoir insured the year-round availability of water. The dam provided human control over the river in a way that prevented floods and rendered it navigable. Generators were put in place, and the power plant supplied pollution-free electricity to southern California, Nevada, and Arizona. As a bonus for residents, profits from the sale of electricity were used to fund other projects and therefore reduced their taxes. The success of Hoover Dam prompted government officials to fund other large construction projects.

When the dam was completed in 1936, it stood 726 feet (221 meters) high with a crest width of 1,244 feet (379 meters). Designers went beyond functionality in creating the breathtaking colossal structure. They also included a flair of artistic expression that could be seen in the elegance of its arch-gravity wall, which was a wall with the characteristics of both an arch dam and a gravity dam. The Hoover Dam curved upstream in a narrowing curve that directed most of the water pressure against the canyon walls that, in turn, fortified the dam by compressing it. The total cost of the dam was \$49 million. Internationally, the dam was recognized as an engineering marvel. It was not surprising that Hoover Dam was declared an American historical landmark in 1985. It has remained a popular tourist attraction since it opened. In 1995, dam administrators opened a new visitor center and a new parking structure for the public.

In a more general sense, large works projects like the Hoover Dam that provided a dependable supply of water and electricity often encouraged urbanization, industrialization, and economic growth. Many people were attracted to such areas for construction jobs, and urban centers grew as population grew. After the large work projects were completed, entrepreneurs wishing to establish factories were attracted to these areas by the availability of a large labor force. New factories created more jobs.

Although the Hoover Dam, like other large works projects, created many benefits, some people questioned whether the dam also produced costs, especially to the environment. Studies of the ecosystem (plants and animals in the water habitat) showed that human control of the natural environment had caused changes to the chemical, physical, and biological processes along the Colorado River. Most notably, environmental scientists concluded that the dam had contributed to the decline in population of certain species of fish. Critics of the studies argued that the benefits from Hoover Dam outweighed the costs. They pointed out that human control of the river with the use of the dam had saved thousands of human lives (as well as lives in the ecosystem) from floods and droughts and had contributed greatly to economic development in the region.

In the 1990s, officials began planning a bypass bridge project to alleviate traffic bottlenecks near the

dam. Besides securing funding for the massive undertaking of building a bridge over the Black Canyon, the biggest obstacle was designing a new functional structure that did not detract from the grandeur of the existing landmark. Builders adopted a sleek bridge design with an arched suspension. The construction project began in 2005, was completed in 2010, and was named the Mike O'Callaghan–Pat Tillman Memorial Bridge in honor of a Nevada governor and an Arizona football player who joined the military and died fighting in Afghanistan in 2004.

Visitors to Hoover Dam could see a bridge soaring dramatically across the canyon. In like manner, commuters on the bridge were able to see the dam from a new impressive height and angle. Although some people disliked the addition, others applauded it. In recent years, China's Three Gorges Dam surpassed the massive size of Hoover Dam. Rogun Dam in Tajikistan has also surpassed Hoover Dam's height. However,

Hoover Dam has remained an engineering marvel and an important American icon.

Primary Document: President Franklin D. Roosevelt's Speech at the Dedication of Hoover Dam (1935)

Hoover Dam was built between 1931 and 1936 on the Colorado River near the Nevada and Arizona border. Although begun under President Herbert Hoover, the dam became part of President Franklin D. Roosevelt's "New Deal for Americans," a plan to put people back to work in the midst of the Great Depression. The following is Roosevelt's speech at the 1935 dedication event for the dam, which Roosevelt called "Boulder Dam."

Senator Pittman, Secretary Ickes, Governors of the Colorado's States, and you especially you have built Boulder Dam, this morning I came, I saw and I was conquered, as everyone would be who sees for the first time this great feat of mankind.

Ten years ago the place where we are gathered was an unpeopled, forbidding desert. In the bottom of a gloomy canyon, whose precipitous walls rose to a height of more than a thousand feet, flowed a turbulent, dangerous river. The mountains on either side of the canyon were difficult of access with neither road nor trail, and their rocks were protected by neither trees nor grass from the blazing heat of the sun. The site of Boulder City was a cactus-covered waste.

the transformation wrought here in these years is a twentieth-century marvel.

We are here to celebrate the completion of the greatest dam in the world, rising 726 feet above the bed-rock of the river and altering the geography of a whole region; we are here to see the creation of the largest artificial lake in the world—115 miles long, holding enough water, for example, to cover the state of Connecticut to a depth of ten feet; and we are here to see nearing completion a power house which will contain the largest generators and turbines yet installed in this country, machinery that can continuously supply nearly two million horsepower of electric energy.

All these dimensions are superlative. They represent and embody the accumulated engineering knowledge and experience of centuries; and when we behold them it is fitting that we pay tribute to the genius of their designers. We recognize also the energy, resourcefulness and zeal of the builders, who, under the greatest physical obstacles, have pushed this work forward to completion two years in advance of the contract requirements. but especially,

we express our gratitude to the thousands of workers who gave brain and brawn to this great work of construction.

Beautiful and great as this structure is, it must also be considered in its relationship to the agricultural and industrial development and in its contribution to the health and comfort of the people of America who live in the southwest.

To divert and distribute the water of an arid region, so that there shall be security of rights and efficiency in service, is one of the greatest problems of law and of administration to be found in any Government. The farms, the cities, the people who live along the many thousands of miles of this river and its tributaries—all of them depend upon the conservation, the regulation, and the equitable division of its ever-changing water supply.

What has been accomplished on the Colorado in working out such a scheme of distribution is inspiring to the whole country. Through the cooperation of the States who people depend upon this river, and of the Federal Government which is concerned in the general welfare, there is being constructed a system of distributive works and of laws and practices which will insure to the millions of people who now dwell in this basin, and the millions of others who will come to dwell here in future generations, a just, safe, and permanent system of water rights. In devising these policies and the means for putting them into practice the Bureau of Reclamation of the Federal Government has taken, and is destined to take in the future, a leading and helpful part. The bureau has been the instrument which gave effect to the legislation introduced in Congress by senator Hiram Johnson and Congressman Phil Swing.

As an unregulated river, the Colorado added little of value to the region this dam serves. when in flood the river was a threatening torrent. In the dry months of the years it shrank to a trickling stream. For a generation the people of the Imperial Valley had lived in the shadow of disaster from this river which provided their livelihood, and which is the foundation of their hopes for themselves and their children. Every spring they awaited with dread the coming of a flood, and at the end of nearly every summer they feared a shortage of water would destroy their crops.

The gates of these great diversion tunnels were closed here at Boulder Dam last February. In June a

great flood came down the river. It came roaring down the canyons of the Colorado, was caught and safely held behind Boulder Dam.

Last year a drought of unprecedented severity was visited upon the West. The watershed of this Colorado River did not escape. In July the canals of the Imperial Valley went dry. Crop losses in that Valley alone totaled \$10,000,000 that summer. Had Boulder Dam been completed one year earlier, this loss would have been prevented, because the spring flood would have been stored to furnish a steady water supply for the long dry summer and fall.

Across the San Jacinto Mountains southwest of Boulder Dam, the cities of southern California are constructing an aqueduct to cost \$220,000,000, which they have raised, for the purpose of carrying the regulated waters of the Colorado River to the Pacific Coast 259 miles away.

Across the desert and mountains to the west and south run great electric transmission lines by which factory motors, street and household light and irrigation pumps will be operated in Southern Arizona and California. Part of this power will be used in pumping the water through the aqueduct to supplement the domestic supplies of Los Angeles and surrounding cities.

Navigation of the river from Boulder Dam to the Grand Canyon has been made possible, a 115-mile stretch that has been traversed less than half a dozen times in history. an immense new park has been created for the enjoyment of all our people.

At what cost was this done? Boulder Dam and the power houses together cost a total of \$108,000,000, all of which will be repaid with interest in fifty years under the contracts for sale of the power. Under these contracts, already completed, not only will the cost be repaid, but the way is opened for the provision of needed light and power to the consumer at reduced rates. In the expenditure of the price of Boulder Dam during the depression years work was provided for 4,000 men, most of them heads of families, and many thousands more were enabled to earn a livelihood through manufacture of materials and machinery.

And this is true in regard to the thousands of projects undertaken by the Federal Government, by the states and by the counties and municipalities in recent years. The overwhelming majority of them are of definite and permanent usefulness.

Throughout our national history we have had a great program of public improvements, and in these past two years all that we have done has been to accelerate that program. We know, too, that the reason for this speeding up was the need of giving relief to several million men and women whose earning capacity had been destroyed by the complexities and lack of thought of the economic system of the past generation.

No sensible person is foolish enough to draw hard and fast classifications as to usefulness or need. Obviously, for instance, this great Boulder Dam, warrants universal approval because it will prevent floods and flood damage, because it will irrigate thousands of acres of tillable land and because it will generate electricity to turn the wheels of many factories and illuminate countless homes.

But can we say that a five foot brushwood dam across the head waters of an arroyo, and costing only a millionth part of Boulder Dam, is an undesirable project or a waste of money? Can we say that the great brick high school, costing \$2,000,000, is a useful expenditure but that a little wooden school house project, costing five or ten thousand dollars, is a wasteful extravagance? Is it fair to approve a huge city boulevard and, at the same time, disapprove the improvement of a muddy farm-to-market road?

While we do all of this, we give actual work to the unemployed and at the same time we add to the wealth of the Nation. These efforts meet with the approval of the people of the Nation.

In a little over two years this work has accomplished much. We have helped mankind by the works themselves, and, at the same time, we have created the necessary purchasing power to throw in the clutch to start the wheels of what we call private industry. Such expenditures on all of these works, great and small, flow out to many beneficiaries. They revive other and more remote industries and businesses. Money is put in circulation. Credit is expanded and the financial and industrial mechanism of America is stimulated to more and more activity.

Labor makes wealth. The use of materials makes wealth. To employ workers and material when private employment has failed is to translate into great national possessions the energy that otherwise would be wasted. Boulder Dam is a splendid symbol of that principle. The mighty waters of the Colorado were

running unused to the sea. Today we translate them into a great national possession.

I might go further and suggest to you that use begets use. Such works as this serve as a means of making useful other national possessions. Vast deposits of precious metals are scattered within a short distance of where we stand today. They await the development of cheap power.

These great government power projects will affect not only the development of agriculture and industry and mining in the sections that they serve, but they will also prove useful yardsticks to measure the cost of power throughout the United States. It is my belief that the government should proceed to lay down the first yardstick from this great power plant in the form of a state power line, assisted in its financing by the government, and tapping the wonderful natural resources of Southern Nevada. Doubtless the same policy of financial assistance to State authorities can be followed in the development of Nevada's sister State, Arizona, on the other side of the river.

With it all, with work proceeding in every one of the more than three thousand counties in the United States, and of a vastly greater number of local division of government, the actual credit of government agencies is on a stronger and safer basis than at any time in the past six years. many States have actually improved their financial position in the past two years. Municipal tax receipts are being paid when the taxes fall due, and tax arrearages are steadily declining.

It is a simple fact that government spending is already beginning to show definite signs of its effect on consumer spending; that the putting of people to work by the government has put other people to work through private employment, and that in two years and a half we have come to the point today where private industry must bear the principal responsibility of keeping the processes of greater employment moving forward with accelerated speed.

The people of the United States are proud of Boulder Dam. With the exception of the few who are narrow visioned, people everywhere on the Atlantic Seaboard, people in the Middle West and the Northwest, people in the South, must surely recognize that the national benefits which will be derived from the completion of this project will make themselves felt in every one of the forty-eight states. They know that

poverty or distress in a community two thousand miles away may affect them, and equally that prosperity and higher standards of living across a whole continent will help them back home.

Today marks the official completion and dedication of the Boulder Dam, the first of four great government regional units. This is an engineering victory

of the first order—another great achievement of American resourcefulness, American skill and determination.

That is why I have the right once more to congratulate you who have built Boulder Dam and on behalf of the Nation say to you, “Well done.”

Hydrogen Bomb

Hydrogen bombs derive their power from fusion, which is the same driving force of the sun. Also referred to as thermonuclear bombs, hydrogen bombs force together hydrogen isotopes (deuterium and tritium) to create a blast that is thousands of times more powerful than atomic bombs. By forcing hydrogen isotopes together, the potential amount of energy that can be released by a hydrogen bomb is enormous; some have even described it as limitless.

Hydrogen bombs are a combination of two bombs. For the hydrogen isotopes to be smashed together to start a nuclear chain reaction, a large amount of heat is needed. This necessary heat is obtained from an atomic bomb within the hydrogen bomb. The atomic bomb triggers the hydrogen bomb, and the explosions of each occur almost instantaneously.

Hydrogen bombs have never been used in warfare, but the potential for damage caused by this type of thermonuclear weapon is almost unfathomable. The devastation felt by Japan after the atomic bombs were dropped on Hiroshima and Nagasaki were nothing compared to the destruction that would be caused by a detonated hydrogen bomb. To put its power into perspective, the Nagasaki bomb, the bigger of the atom bombs dropped on Japan, measured 21 kilotons. This is equal to the force of 21,000 tons of TNT. The Tzar Bomb, which was the biggest hydrogen bomb ever detonated, measured 50,000 kilotons. This bomb detonated by Russia was equal to 50,000,000 tons of TNT. That is over 2,300 times more powerful than the bomb dropped on Nagasaki.

The potential dangers and merits of developing a hydrogen bomb were widely discussed and a consensus was ultimately reached that scientists should not

pursue its production. Such development was highly controversial, and many scientists fought against it, including Enrico Fermi and Isidor Rabi. The duo said this of hydrogen bombs: “Since no limit exists to the destructiveness of this weapon, its existence and knowledge of its construction is a danger to humanity as a whole.”

In the early stages of the bomb’s development, President Truman attempted to keep information about it from the public and instructed anyone involved with the project to avoid mentioning it to the press. Word got out, however, and President Truman was forced to announce his decision to move forward with the hydrogen bomb to the American people. Truman stated that he felt there was no alternative to proceeding with the development of atomic weapons, largely because of the Soviet Union’s failed detonation of an atomic device. The arms race between the United States and the Soviet Union was heightened as each country openly began its research and development of hydrogen bombs.

Over the years, several hydrogen bombs have been tested. As of 2016, the United States, Russia, the United Kingdom, China, and France have hydrogen bombs in their possession, making it challenging to attempt to ban nuclear testing and reduce nuclear arms.

Hydroponics

Hydroponics means “working water,” deriving from the Latin words “*hydro*,” meaning water, and “*ponos*,” meaning labor. Hydroponics is a subset of hydroculture; it is better known as soilless gardening. It is a method of growing plants without soil and feeding them with mineral nutrient solutions, usually in water but not always. Hydroponics provides plants with nutrition and hydration through the flow of oxygen and also water that is nutrient rich. In this system, water goes directly to the roots, where it can be quickly absorbed; but plants need more than just nutrients in this method, such as proper air circulation so that plants can receive carbon dioxide and be protected from mold and bacteria.

The hydroponic method can be used anywhere—inside, outside, or in a greenhouse. With this technique, there are fewer limitations as compared to the “normal” way of planting: plants can be grown in any climate or conditions. This is why hydroponics has become more popular during drastic times.

This method is believed to date back to ancient Rome during the first century CE, when certain minerals were used to grow plants in any season, because the emperor at this time demanded certain flowers to fill his garden. The hydroponics method was used to keep the garden filled year-round. These techniques were used throughout the world in places such as ancient Egypt, Babylonia, China, and also by the Aztecs in Mesoamerica.

However, the technique disappeared and did not reappear until John Woodward began experimenting with it in 1699. He grew mint plants without soil. Woodward’s work would become the foundation of modern hydroponics. The next recorded experiments would not come until 1859 to 1865, when German scientists Julius von Sachs and Wilhelm Knop worked on growing plants with nutrients in a solution.

In the United States, hydroponic work began in 1925, but it was not given this name until 1929, when Dr. F. Gericke achieved success and created a variety of commercial crops without soil. Hydroponics was used during World War II to feed soldiers and is still used today. Hydroponics produces food more easily

because climate is not a factor. Famously, the Disney Company began using a large-scale hydroponic system in its EPCOT (now Epcot) theme park in Orlando, Florida, in 1982. The Disney park uses different methods of hydroponics, including aeroponics and aquaponics; both of these produce amazing crops. Various hydroponic methods are still being discovered.

There are two main methods of hydroponics: solution culture, using only a solution for feeding roots; and medium culture, with a solid medium for roots that is sub or top irrigated and in a container. Many systems of hydroponics have arisen over time. These include the wick system, water culture, the ebb-and-flow system, the drip system, the nutrient film technique (NFT) system, and the aeroponic system.

The simplest is the wick system, which has no moving parts. The plants are submerged underwater, where they receive nutrients. The wick system is efficient, easy, and cheap to maintain. One drawback is that it cannot maintain complex plants; it works well with small ones that need less water, such as lettuce. Another simple system is the water culture system, in which plants are suspended right over the nutrient solution with only their roots hanging in it. Plants get the air and nutrients they need.

The ebb-and-flow system is sometimes known as “flood and drain” and is one of the most widely used methods. Plants are placed in a tray that is periodically filled with nutrient-rich water pumped out of a reservoir, and gravity returns the water to the reservoir to be reused. This method is a little more complex because of its components but it is useful because it can easily support many plants. The drip system is widely used by both homeowners and commercially because it is simple. It is used for large plants that require lots of root space.

The NFT system is similar to the wick and the ebb-and-flow systems. Water is pumped to the grow tray, and a drainpipe is used to recycle the nutrient solution; the nutrient solution flows continuously to the roots with the help of gravity. NFT works best with plants that do not rely much on light. The aeroponic system is much discussed today; it is a high tech method. This system’s growing medium is primarily air; the roots hang in the air and are misted with nutrient solution, directly delivered with no waste. The

system uses only 2 percent of the water that regular gardening does. Many more systems are being developed as well.

The biggest benefit of hydroponics is that plants can be produced all year round instead of in a single season. Studies have shown that this method produces larger harvests, faster. Crops do not take up as much space and can be moved easily. Many other benefits of hydroponics may continue to become apparent.

International Ladies' Garment Workers' Union (ILGWU)

The International Ladies' Garment Workers' Union (ILGWU) arose during an era when American industry provided few worker protections. In its earliest incarnation, repulsed by the inequality created by unchecked capitalism, the ILGWU turned to socialism to promote a fair future for all workers. Though the ILGWU represents primarily women, men have played a role in its membership and success, and it reached a peak membership of 450,000 in 1969.

Danish American social reformer Jacob Riis (1849–1914) used the term "sweatshop" to describe conditions in the garment industry, where the seven-day workweek, arbitrary hours, and meager pay were the norm in an America where business regulated itself. On March 11, 1900, the United Brotherhood of Cloak Makers' Union No. 1 convened a meeting that created the ILGWU to combat the inequities of sweatshops. Herman Grossman was the union's first president. Jewish women and immigrant women, notably Italian women, were large constituencies of the ILGWU. One of the ILGWU's first acts was to create an education division to increase literacy among immigrant women.

In 1909, the ILGWU participated in the Uprising of 20,000, a 14-week strike against garment employers for improved hours, wages, and working conditions. Strike leader Clara Lemlich demanded that the entire garment industry be shut down by a worker walkout. Female garment workers enthusiastically responded. Employers tried to crush the strike by hiring replacements. The ILGWU could do little to help, having only \$4 in its treasury at the time. The union gained deeper support for its mission of providing safer workplaces after the tragedy of the Triangle Shirtwaist Factory Fire of 1911.

In the 1910s, the ILGWU sought to attract members nationwide, not merely in New York City. As part of its effort to move west, the union sought to organize in Cleveland, Ohio, which was then the nation's fourth-largest center of garment making. The ILGWU members went on strike in 1911 to seek recognition as the sole bargainer for women garment workers. As before, garment shops used scab or nonunion labor and police intimidation to try to break the strike. The ILGWU pointed to the Triangle Shirtwaist Fire in 1911 as evidence of the dangerous and even deadly working conditions under which poor women labored.

In 1914, the ILGWU opened a health clinic, perhaps the first union clinic in the United States. The clinic devoted much of its resources to combating tuberculosis, then an incurable, frightening disease rampant among textile workers because of poor conditions in factories. In the 1920s, many ILGWU women joined the Socialist Party. Tensions between socialists and nonsocialists threatened to divide the union. Socialists within the union wanted to encourage a nationwide revolution by restructuring American government, whereas nonsocialists sought change within the nation's existing political structure.

Despite the Great Depression, the ILGWU was able to negotiate favorable contracts and raise money. The Great Migration of black Americans, most of them poor, from the South to Northern states meant that black women began to work in the garment industry. The ILGWU was initially intolerant of these new workers, in part because racism was not confined to the South and in part because white workers worried about losing their jobs if employers found that they could pay black women even less. As African Americans took

leadership roles, however, they were able to blunt the organization's racism. ILGWU organizer Frank Crossaith formed the Negro Labor Committee to give voice to African American women.

In the 1930s, the ILGWU formed locals in Puerto Rico and Canada. The union supported the New Deal and joined the Congress of Industrial Organization (CIO). The ILGWU was also a member of the American Federation of Labor (AFL) at a time when a union typically joined one or the other but not both. From the outset, the ILGWU believed that the AFL and the CIO should merge, given that a large aggregation of unions would be stronger than many small unions. The ILGWU realized this ambition in 1955 with the merger of the AFL and CIO.

During World War II, the ILGWU opposed the rise of Nazism, fascism, and imperialism in the East. In particular, Italian women in the ILGWU rejected Italian fascist Benito Mussolini (1883–1945). After the war, the ILGWU aimed to help Italy rebuild along democratic lines. As part of the postwar move to the suburbs, the ILGWU funded the construction of new homes for its members.

After the war, the United States moved toward free trade. Third-world economies, clinging to the sweatshop, gained entry into U.S. markets. Cheap imports competed with ILGWU-produced clothes. American clothiers, eager to bypass the ILGWU, moved to Mexico and Asia. The third world could make clothes for about a twentieth of the cost of U.S. union workers. In 1984, wages for garment workers were \$7 per hour in the United States, \$1 per hour in Mexico, 21 cents per hour in China, and 12 cents per hour in Bangladesh. As is often the case, manufacturers put profits ahead of people, and American consumers failed to object to the inequities that this shift

caused, both for American and foreign workers, in part because it encouraged consumer culture with a flood of cheap goods.

These changes in economic policy weakened the ILGWU. By 1994, membership had declined to 125,000. This trend is part of a larger story in which the number of garment workers in the United States has declined, wages have flattened, and imports have flooded the domestic market, allowing retailers to increase their markups and consumers to buy more disposable goods.

By the late 20th century, New York City estimated that some 3,000 garment makers did not pay minimum wage, forcing the U.S. Department of Labor to try to collect more than \$2.3 million in lost wages for 8,000 workers. Immigrants from Latin America and Asia have taken jobs in the garment industry, creating further downward pressure on wages. Recently a move toward educating American consumers about the dangers to workers, combined with environmental realities caused by cheap and plentiful consumer goods, has begun to address these issues. Nonetheless, worker abuses and deaths in overseas garment factories in the 21st century suggest that much remains to be done.

Primary Document: "The Uprising of the 20,000"

The New York Shirtwaist Strike of 1909, also called "The Uprising of the 20,000," set the standard for female labor organizing in the early 20th century and for garment industry unions. The strike, featured in the song here, contributed to the ILGWU's rapid growth in the 1910s.

The Uprising of the Twenty Thousand
Dedicated to the Waistmakers of 1909

In the black of the winter of nineteen nine,
When we froze and bled on the picket line,

We showed the world that women could fight
And we rose and won with women's might.

Chorus:

Hail the waistmakers of nineteen nine,
Making their stand on the picket line,
Breaking the power of those who reign,
Pointing the way, smashing the chain.

And we gave new courage to the men
Who carried on in nineteen ten
And shoulder to shoulder we'll win through,
Led by the I.L.G.W.U.

Interstate Highway System

The interstate highway system both represented and fueled the changing patterns of life and work in the post–World War II United States. A model of federalism, an example of the federal and state governments working together, the American highway system was a network of integrated major highways that still allows motorists to travel easily about the country. It is a system that both represents the impact of the automobile on American society and serves to further enhance the centrality of the car in American life.

Substantive interest in some kind of expansive, coordinated national system of highways in the United States can be traced back to the mid-1920s. Initial talk of coordinating existing state networks led to discussions about the creation of a true national system. These preliminary discussions reflected the increased use of the automobile as well as the nation's growth and changing demographics. And, as the Great Depression deepened, the job creation potential of such a project added to its political appeal. However, at their most advanced stage, the early discussions focused only on three east-west and three north-south routes. With the passage by Congress of the Federal-Aid Highway Act of 1938, formal consideration of a federally coordinated system, however limited its reach, began. Under that law, the Bureau of Public Roads (BPR) was directed to study the feasibility of such a six-route toll network. The BPR report, *Toll Roads and Free Roads*, was submitted to Congress in 1939, and although it concluded that such a system could not be self-supporting and instead urged a less extensive network, it represented the first formal concept of an interstate highway system. While the nation's increasing

mobilization for World War II put many things on the back burner, in 1941, President Franklin Roosevelt appointed a National Interregional Highway Committee and named BPR head Thomas MacDonald as chairman. The group's 1944 report refined the earlier Interstate Highway concept, and in response, Congress took the step that, earlier forays notwithstanding, marked the start of the modern system, passing the Federal-Aid Highway Act of 1944, a law that authorized construction of a 40,000 mile "National System of Interstate Highways" intended to connect the nation's cities. The plan also included the establishment of an additional system of principal secondary and feeder roads.

In reality, this legislation was something of a false start, for it included no funding mechanism. Instead, it was intended to serve as a statement, a reflection of a national commitment, with states expected to make highway construction a top-priority item on their lists for spending federal aid funds. However, with numerous other postwar needs, states devoted few funds to road construction.

The first funding for the national highways came in legislation enacted in 1952. That law, the Federal-Aid Highway Act of 1952, authorized a paltry \$25 million a year for the fiscal years 1954 and 1955. The law also called for a 50-50 state/federal matching funding plan. The Federal-Aid Highway Act of 1954 upped the nation's investment considerably. This version raised the authorization to \$175 million a year while changing the federal-state ratio to 60-40. However, all of this paled in comparison to the legislation passed in June 1956, when, after years of political maneuvering, Congress passed a new version of the Federal-Aid Highway Act. This version dedicated

\$26 billion to financing the 41,000 miles of highway that were intended to go from coast to coast. The funding was to come from a tax on each gallon of gas, and the federal government would foot the bill for 90 percent of the highway creation. To protect the fund, and recognizing that the project would not end with the building of the road but that maintenance would be necessary, the Federal-Aid Highway Act of 1956 that authorized the construction and the spending was aided by the enactment of the Highway Revenue Act of 1956, which was not technically a separate piece of legislation but rather a supplemental one that contained the funding mechanism by which the user taxes would be set aside for future highway purposes. The legislation, sponsored by Louisiana Democratic congressman Hale Boggs, established a Highway Trust Fund that was modeled on the Social Security Trust Fund. Reflective of the Congressional and administration cooperation that characterized the effort, the trust fund idea had been a suggestion of Eisenhower's Treasury secretary, George Humphrey.

In addition to authoring the construction of an interstate highway network as well as a mechanism for the funding, the 1956 act established national standards for design. Among these were a minimum of two lanes in each direction. The lanes themselves had to be at least 12 feet wide with a 10-foot right-side paved shoulder. They were also intended to accommodate speeds of 50 to 70 miles per hour; these high speeds were intended to eliminate congestion. There were to be no at-grade crossings—only over- and underpasses to facilitate both safety and speed. The goals of these efforts were to make coast-to-coast travel easier, facilitate city evacuation in case of atomic attack, and replace slums with more attractive “ribbons of concrete.”

The government's support of this national network of highways made their construction easier and fueled a national building boom. The boom was not limited to the highways. Rather, the increased highway mileage contributed to a major change in the nation's residential and housing development patterns, accelerating the already developing shift to the suburbs.

When John Kennedy came into office in 1961, the system developed funding issues. In 1959, President Eisenhower signed into legislation to raise the federal gas tax to pay for the Interstate System. When the tax

was set to expire in 1961, President Kennedy asked Congress to make the tax permanent.

While the future existence of the system was assured, the Kennedy administration had to turn its attention to some of the developing and previously unanticipated objections that had started to emerge. One problem involved charges of corruption. While investigators found that allegations far exceeded reality, such charges undermined public support at a time when the Kennedy administration was making a concerted effort to develop greater public awareness and appreciation for the magnitude and importance of the project to the American economy and way of life. Arguing that each completed interstate highway was the best advertisement the system could offer, the states were urged to keep building in pursuit of the established goals.

While the early responses to the developing network had generally been positive, with the whole system being the beneficiary of widespread public support, as the idea moved from concept and plans to reality, its impact on neighborhoods and cities led to some protests and second thoughts. Indeed, especially problematic was the impact that the new highways sometimes had on local neighborhoods and cities. Organized opposition increasingly emerged as more and more homeowners were displaced and neighborhoods were split in half by the introduction of highways. In a growing number of cases, the result of the introduction of an interstate highway was the abandonment of some part of a city. Active efforts were made to defeat or alter plans, and in some cases, there was success. Evidence of those efforts can be seen today in places where the interstate ends abruptly, resulting in what some critics derisively termed “roads to nowhere.”

In response to the opposition, under Kennedy, new regulations were adopted that called for the Commerce Department to be involved in reviewing issues relating to the displacement of families and businesses. In addition, greater relocation payments were provided. Finally, in a nod to the challenges that came from meshing new highways with the nation's existing urban settings, the Federal-Aid Highway Act of 1962 required that the planning cooperate with local stakeholders.

Another unanticipated obstacle to the developing network was the emerging environmental movement, one fueled by the September 1962 publication of Rachel Carson's *Silent Spring*. While the book dealt

with no issues related to the Interstate System, it opened the public's eyes to the way that human actions impacted the environment, and such a connection was soon made with the ongoing interstate construction and local citizens. Indeed, highway engineers whose previous marching orders had focused on finding the best traffic routes at the lowest cost and with the least disruption of residential area and business districts were suddenly forced to consider the potential environmental impact of their efforts. In fact, in August 1963, BPR issued a directive that, beginning on January 1, 1964, states had to certify that they had considered the potential impact on fish and wildlife of any new Federal-Aid Highway project.

The next step in the ongoing interstate highway system saga came in 1963 with the passage of the Federal-Aid Highway Act of 1963. Although the bill featured little more than technical changes, it did include one provision that reflected the growing size and impact of the system. Whereas the original 1956 legislation had called on highway engineers to design roads capable of meeting the traffic demand in 1975, concern about the system soon becoming obsolete led to a provision in the 1963 act calling for a design that would carry the project 20 years into the future.

While the process had become more complicated and the factors affected by each mile of completed highway had grown, the project continued toward completion, stretching to the far corners of the nation, north and south, east and west, throughout the 1960s and into the 1970s. Subsequent legislation has expanded the original plan, creating new routes in places previously ignored as the nation's demographics have changed.

The importance of a national highway system caused Congress to create the Department of Transportation in 1966 with its secretary, one of whose

major responsibilities was the oversight of the Interstate System, joining the presidential cabinet. Too, its reach was highlighted in another way when First Lady "Lady Bird" Johnson sought to beautify the nation by prohibiting billboard advertising along the interstates. However, the initiative had only limited and short-lived success as the captive audience provided by the thousands of miles of landscape and the millions of passing drivers/consumers was too strong a commercial force to allow for a total prohibition.

In 1990, in acknowledgment of the critical role he played in the development of the system, legislation was enacted that officially designated the system the Dwight D. Eisenhower System of Interstate and Defense Highways.

With the formal framework fully established and the funding in place, the progress toward completion continues. With the familiar three-digit beltways that circle the nation's major urban areas, routes that can take travelers through a succession of states, and the almost 43,000 miles of highway that it includes, the U.S. Interstate Highway System is a reflection of a people that is at once independent and interdependent but always on the move.

Pfeiffer, David A. 2006. "Ike's Interstates at 50: Anniversary of the Highway System Recalls Eisenhower's Role as Catalyst." *Prologue Magazine* 38, no. 2 (Summer).

Primary Document: Excerpt from the Federal-Aid Highway Act (1956)

Though most Americans no longer remember this, the Interstate Highway System was proposed and built, in part, to aid in national defense. Post–World War II politicians, in the midst of a Cold War with the Soviet Union, believed it was essential that the nation be able to swiftly move the military and its supplies around the nation by way of a highway system. The

following is an excerpt of the Federal-Aid Highway Act of 1956, signed into law by President Dwight D. Eisenhower.

Enrolled Acts and Resolutions of Congress, 1789–1996; General Records of the United States Government; Record Group 11; National Archives

Sec. 108. National System of Interstate and Defense Highways.

(a) Interstate System. It is hereby declared to be essential to the national interest to provide for the early completion, of the National System of Interstate Highways, as authorized and designated in accordance with section 7 of the Federal-Aid Highway Act of 1944 (58 Stat. 838). It is the intent of the Congress that the Interstate System be completed as nearly as practicable over a thirteen-year period and that the entire System in all the States be brought to simultaneous completion. Because of its primary importance to the national defense, the name of such system is hereby changed to the National System of Interstate and Defense Highways. Such National System of Interstate and Defense Highways is hereinafter in this Act referred to as the Interstate System.

(b) Authorization of Appropriations. For the purpose of expediting the construction, reconstruction or improvement, inclusive of necessary bridges and tunnels, of the Interstate System, including extensions thereof through urban areas, designated in accordance with the provisions of section 7 of the Federal-Aid Highway Act of 1944 (58 Stat. 838), there is hereby authorized to be appropriated the additional sum of

\$1,000,000,000; for the fiscal year ending June 30, 1957, which sum shall be in addition to the authorization heretofore made for that year, the additional sum of \$1,700,000,000 for the fiscal year ending June 30, 1958, the additional sum of \$2,000,000,000 for the fiscal year ending June 30, 1959, the additional sum of \$2,200,000,000 for the fiscal year ending June 30, 1960, the additional sum of \$2,200,000,000 for the fiscal year ending June 30, 1961, the additional sum of \$2,200,000,000 for the fiscal year ending June 30, 1962, the additional sum of \$2,200,000,000 for the fiscal year ending June 30, 1963, the additional sum of \$2,200,000,000 for the fiscal year ending June 30, 1964, the additional sum of \$2,200,000,000 for the fiscal year ending June 30, 1965, the additional sum of \$2,200,000,000 for the fiscal year ending June 30, 1966, the additional sum of \$2,200,000,000 for the fiscal year ending June 30, 1967, the additional sum of \$1,500,000,000 for the fiscal year ending June 30, 1968, and the additional sum of \$1,025,000,000 for the fiscal year ending: June 30, 1969.

Lamarr, Hedy (1914–2000)

More than a Hollywood star, Hedy Lamarr was one of the most influential female inventors of the 20th century. She invented spread spectrum technology, the basis for worldwide wireless communication systems.

Born Hedwig Eva Maria Kiesler to upper-middle-class Jewish parents in Vienna, Austria, Lamarr was always intrigued with how things worked. Acting courses, however, led to her discovery by German theater producer/director Max Reinhardt, and she began acting professionally at age 17. As Hedy Kiesler, she appeared in several German and Czech films, including *Ecstasy* (1933). She became infamous as the “Ecstasy girl” for depicting the first on-screen orgasm. The film was banned in the United States, and Lamarr was labeled sexually provocative.

The same year, Lamarr rocketed to international notoriety, and she married wealthy armaments manufacturer Fritz Mandl. As a member of the Austrian fascist movement, Mandl entertained both Italian dictator Benito Mussolini and the new German chancellor, Adolf Hitler, at his estate. Lamarr was expected to play hostess. Mandl frequently took her to high-level German military meetings. She listened in on discussions regarding engineering challenges for a submarine torpedo guidance system.

One night in 1937, Lamarr escaped both Mandl and Nazi Germany by disguising herself as her maid and fleeing to Paris. After a meeting in London with Louis B. Mayer, head of MGM studios, Lamarr signed a film contract to work in Hollywood. To distance her from her “Ecstasy girl” image, Mayer changed her name to Hedy Lamarr and demanded morality clauses

in her contract. Once in the United States, her divorce was finalized, and she arranged for her mother to join her in California.

In 1940, early in World War II, German submarines began torpedoing civilian ships. Remembering the flaws in the German torpedo systems, Lamarr determined to contribute to the war effort. She theorized that if a communication transmission could be bounced randomly from one radio frequency to another, it would be impossible to intercept, decode, or jam the communication. However, she was challenged by how to synchronize the randomly changing frequencies between both the sender and the receiver of the communication.

Lamarr met avant-garde composer and pianist George Antheil in Hollywood. Antheil, the son of German immigrants, had composed *Ballet mécanique* using synchronized player pianos. With the rise of the Nazi Party, he fled Germany. The two combined Lamarr's idea of frequency hopping with a mechanism similar to a roll on a player piano. Lamarr and Antheil filed for and received a patent for a "Secret Communications System" in August 1942.

Lamarr and Antheil offered their invention to the U.S. Navy but were rebuffed. Officials may have been biased against an idea created by two Hollywood entertainers, one of them a famous female actor. Lamarr also offered to participate on the National Inventions Council to aid the war effort but was advised that she could accomplish more using her celebrity to raise funds selling war bonds. She went on to raise \$7 million for the war effort in a single evening.

Lamarr's invention of frequency hopping, or spread spectrum technology, sat unused for decades. The patent expired in 1960. In 1962, technological advances in microprocessors made frequency hopping feasible, and the technology was used to secure American military radio transmissions during the Cuban Missile Crisis. Today, U.S. defense communication satellites, cellular phones, the Global Positioning System (GPS), and other wireless communication systems all employ Lamarr's technological invention. The technology is also used in integrated bar code scanners, handheld computers, computer data, and e-mail.

During her Hollywood film career, Lamarr appeared in over 20 movies. She felt that her beauty and

Though Hedy Lamarr is best remembered as a film actress of the 1930s and 1940s, she was also a talented inventor. The frequency hopping technology she developed in 1942 is now used in Bluetooth and Wifi technologies. (Sunset Boulevard/Corbis via Getty Images)

early notoriety had caused her to be cast as an immoral vixen. The fixation on her physical beauty over her intellect may also have sabotaged her self-image; she was married and divorced six times. She continued inventing throughout her life—a kind of traffic light, a fluorescent dog collar, modification ideas for the supersonic Concorde plane, and more.

Neither Lamarr nor Antheil received any financial benefit from their invention. In 1997, Lamarr and Antheil received the Electronic Frontier Foundation Pioneer Award, and Lamarr became the first woman to receive the BULBIE Gnass Spirit of Achievement Award (a lifetime achievement award for inventors). Lamarr was inducted into the National Inventors Hall of Fame in 2014, and throughout German-speaking countries in Europe, Inventor's Day is celebrated on her birthday, November 9. Lamarr died in 2000.

Rhodes, Richard. 2011. *Hedy's Folly: The Life and Breakthrough through Invention of Hedy Lamarr, the Most Beautiful Woman in the World*. New York: Doubleday.

Primary Document: Patent for Hedy Lamarr's Frequency-Hopping System (1942)

On June 10, 1941, famed Hollywood actress Hedy Lamarr and composer George Antheil were granted a patent for a frequency hopping system to be used in torpedo guidance systems. Though many sources claim that Lamarr invented frequency hopping, Nikola Tesla had done the original work on frequency hopping some 40 years earlier. Lamarr and Antheil's innovation was to use frequency hopping in a new way. Lamarr, who was known for a time as "the most beautiful woman in the world," invented a number of things in her life, including a new kind of soda pop.

This invention relates broadly to secret communication systems involving the use of carrier waves of different frequencies, and is especially useful in the remote control of dirigible craft, such as torpedoes.

An object of the invention is to provide a method of secret communication which is relatively simple and reliable in operation, but at the same time is difficult to discover or decipher.

Briefly, our system as adapted for radio control of a remote craft, employs a pair of synchronous records, one at the transmitting station and one at the

receiving station, which change the tuning of the transmitting and receiving apparatus from time to time, so that without knowledge of the records an enemy would be unable to determine at what frequency a controlling impulse would be sent. Furthermore, we contemplate employing records of the type used for many years in player pianos, and which consist of long rolls of paper having perforations variously positioned in a plurality of longitudinal rows along the records. In a conventional player piano record there may be 88 rows of perforations, and in our system such a record would permit the use of 88 different carrier frequencies, from one to another of which both the transmitting and receiving station would be changed at intervals. Furthermore, records of the type described can be made of substantial length and may be driven slow or fast. This makes it possible for a pair of records, one at the transmitting station and one at the receiving station, to run for a length of time ample for the remote control of a device such as a torpedo.

Lange, Dorothea (1895–1965)

Documentary photographer Dorothea Lange is known primarily for the work she did on assignment during the Great Depression with the Resettlement Administration/Farm Security Administration from 1935 to 1939, taking pictures of poor and disadvantaged Americans. Lange was prolific throughout her life despite the pressures of marriage, divorce, motherhood, disability, and recurring illness. Photographer Lange took pictures for the Resettlement Administration as part of the New Deal program's efforts to

record the damage that the Great Depression and Dust Bowl did to Americans. Her *Migrant Mother* picture is one of the most famous photos in American history.

Born Dorothea Margareta Nuthorn in 1895 and raised in Hoboken, New Jersey, Lange suffered from polio at the age of seven, which resulted in a lifelong limp. Her father, Henry Nuthorn, abandoned the family when she was 12. Her mother, Joanna "Joan" Caroline Lange, became a librarian to support the family, bringing Lange, who would take her mother's maiden name as her surname, with her on the ferry to attend school on the Lower East Side of Manhattan. Her

father's abandonment and her exposure to the cultural and economic diversity of Manhattan influenced her worldview and her work.

Lange began studying photography in New York City when she was 17. She apprenticed with photographer Arnold Genthe. In 1918, she and her friend Florence Bates left on a trip around the world and made it as far as San Francisco. Lange would live in nearby Berkeley for the rest of her life.

Lange opened a photographic studio in San Francisco in 1919. She was successful as a portraitist for elite-class clientele. In 1920, she married Maynard Dixon, a well-known painter. They had two sons. They traveled together, but Lange discovered that his career took precedence over hers. They began living separately and ultimately divorced after 15 years of marriage.

When the Great Depression began in 1929, Lange felt guilty about the disparity between the wealthy patrons sitting for portraits in her studio and the masses of struggling and jobless Americans. She left her studio and took her camera out into the world. What resulted over the next decades were some of the most iconic and memorable photographs of the 20th century: the *White Angel Breadline*, the instantly recognizable *Migrant Mother*, and Lange's work on many other projects in the western and southern United States as well as in Ireland, the Middle East, and elsewhere.

In 1935, Lange married Paul Schuster Taylor, an economist. Their work dovetailed often, as he studied agriculture under the auspices of the State Emergency Relief Administration (SERA). He hired Lange to photograph the pea harvest in Nipomo, California. She was subsequently hired by the Information Division of the Farm Security Administration (FSA, first known as the Resettlement Administration), run by Roy Stryker, to photograph the living conditions of migrant workers, many of whom had been displaced by poverty or the Dust Bowl in the Midwestern and Southern United States. Her photographs of America's poorest citizens reminded the nation of the dangers of a country with no social welfare safety net and a poorly regulated economy.

In 1942, at the beginning of World War II, Lange was hired by the War Relocation Authority to photograph the relocation of Japanese Americans to internment camps. Together with Ansel Adams, she

photographed the people and living conditions of the entire relocation process before finishing up with work at Manzanar. Her photographs are a stark protest of the cruelty and immorality of the relocation program. Indeed, the photographs proved to be too good and were impounded by the U.S. Army for decades in an effort to hide what they contained.

In 1940, Lange was the first woman to be awarded a Guggenheim Grant, a program that provided promising artists the funds to live for a year and make art. The war interrupted her proposed project, but she took up the work again after the war ended, photographing Mormon communities with her son Daniel Dixon in collaboration with her friend and fellow photographer, Ansel Adams.

Lange struggled with health problems throughout her life, some exacerbated by her bad leg and limp. She considered herself disabled but also considered it a boon in her career, saying that her disability made people nicer to her and more likely to let her photograph them.

Diagnosed with cancer of the esophagus in 1965, Lange spent her last months assembling her life's work for her retrospective at the Museum of Modern Art and helping with a documentary about her life. The exhibition at the Museum of Modern Art in New York opened in 1966, three months after Dorothea Lange died in Berkeley, California.

Lend-Lease Program (1941–1945)

The Lend-Lease Act allowed the United States to provide arms, supplies, and financial assistance to the Allies during World War II (1939–1945). Allied defeat in Europe was probable without U.S. aid, yet President Franklin D. Roosevelt's administration deemed the Act necessary in the face of strong American isolationist tendencies. Although the Act had been originally

developed to aid Great Britain, by the end of the war, 38 nations had received more than \$50 billion of aid. American factories transitioned from making consumer goods to churning out plentiful and innovative war materials, which helped turn the tide of the war.

The Great Depression (1929–1939) devastated the U.S. economy. Many banks and businesses failed, and many Americans lost their jobs and homes. In the 1930s, the Dust Bowl (soil erosion caused by drought and strong winds), which swept through several states, including Texas and Oklahoma, multiplied the hardships faced by farmers. These present troubles, coupled with the memory of American casualties during World War I (1914–1918), reinforced American isolationist tendencies. Consequently, the rise of dictators in Europe and Asia and even the start of World War II did not sway most Americans, who felt that they had enough troubles of their own to contend with. Such was the overwhelming sentiment that U.S. politicians promised constituents that they would see to it that the Atlantic and Pacific Oceans would isolate the United States from other nations' problems.

In 1940, the British prime minister convinced President Roosevelt that Britain would fall to Germany without U.S. aid. Roosevelt believed that a strong Britain was crucial for U.S. security. Britain could not build ships fast enough to keep up with Germany's effective use of submarine technology; consequently, Roosevelt decided to circumvent a series of 1935 Neutrality Acts. In late 1940, Roosevelt issued an executive order to transfer 50 old American destroyers to Britain in exchange for 99-year leases on air and naval bases. Although the United States was still officially neutral, the ships-for-bases deal was the first step away from genuine American neutrality. In early 1941, Roosevelt asked Congress for the power to sell, exchange, lend, or lease war equipment to any nation that was vital to U.S. defense (without a U.S. declaration of war), and Congress granted his request with the Lend-Lease Act.

Before and after the United States officially entered the war in late 1941, many nations benefited greatly from the great quantities of available war materials. For example, the United States provided the Soviets with more than 100,000 railcars and 20,000 aircraft. By the last year of the war, two-thirds of all

Soviet supply trucks were being made in U.S. factories. The Act was also responsible for the availability of innovative war materials. For example, by the end of the war, Allied ships had onboard sonar and radar equipment, which were used to effectively combat German submarine warfare. Besides greatly contributing to Allied victory, one major legacy of the Act was a postwar U.S. economic boom.

Liberty Ships

The “liberty ship” is the name given to the emergency cargo carrier ship manufactured by the U.S. Maritime Commission for use during World War II. The emergency fleet program was an assembly-line production of consistently reliable ships. Liberty ships were nicknamed “ugly ducklings” by President Franklin Delano Roosevelt, but they served their purpose.

Liberty ships were made to meet with British orders for transport ships to replace those destroyed by the German U-boats. In 1941, the steam turbine engine was chosen for these ships because it was more productive than prior steam engines. The ships were assembled of sections welded together. The SS *Patrick Henry* was the first of 2,710 liberty ships launched in 1941; it had taken 150 days to build. The SS *Robert E. Peary* was assembled in four days, 15 hours, and 29 minutes.

The U.S. Navy tested a number of liberty ships in the North Atlantic. Three ships developed cracks severe enough to break into two parts, while 1,500 other ships developed small hull fractures. Yet, more than 2,400 liberty ships endured the war. Of the 2,400, 835 made up the postwar cargo fleet, and 200 disappeared during World War II due to accidents and battles.

Originally, liberty ships were made to last up to five years, but some still sail today. Two are active: the SS *Jeremiah O'Brien* in San Francisco, California, at Pier 45 on Fisherman's Wharf; and the SS *John W.*

Brown in Baltimore, Maryland. Both are open for the public to tour. In 2011, the United States Postal Service issued a set of Merchant Marine stamps, one of which was a liberty ship.

M&M's

A classic, iconic American candy with a hard shell and chocolate filling inside, the M&M was first introduced in the 1940s and is now distributed in over 100 countries. Its inventor, Forrest Mars, conjured up the idea in the 1930s upon witnessing soldiers eat hard-shelled candies called “smarties,” which were made from saccharine or syrup. He then further developed his own formula that used milk chocolate instead of syrup. He patented his candy with the hard shell and milk chocolate filling in 1941.

The company used the hard candy shell feature in its advertising campaign, which said, “The milk chocolate melts in your mouth—not in your hand.” This appealed to soldiers and parents equally. In the 1950s, the company introduced an M printed on the hard shell, which became a well-recognized trademark. In the 1980s, M&M's began their international journey to countries such as Australia, Canada, the United

Kingdom, Europe, Hong Kong, and Japan. Peanut M&M's were introduced in the 1950s and almond M&M's in the 1960s. Almond M&M's were taken off the market soon after their introduction and not reintroduced until the 1980s. In the 1990s, M&M's introduced peanut butter–filled M&M's, crispy M&M's, and M&M minis. In the 2010s, the company introduced pretzel M&M's, caramel M&M's, and the M&M chocolate bar.

M4 Sherman Tank

The M4 Sherman tank was broadly used throughout all theaters of war in World War II. It was the first American tank to incorporate a 360-degree mounted turret. In its final version, the tank was released into war with a 75mm gun, and the engine that drove the tank was a Continental R975 engine, which was air-cooled and produced 400 horsepower. Steering was by a dedicated driver positioned with a frontal view, either through a front hatch when out of combat or through a small, cutout slit in the armor.

Production of the Sherman medium tank started in February 1942. Further testing was conducted on the M4 under the Steel Car Company and the Pacific Car and Foundry Company. After testing, the M4 was dubbed combat worthy and given the new name M4A1. The United States then produced 6,281 of them with the 75mm gun. The main difference between the M4 and the M4A1 is that the M4 has a welded, angular upper hull, which can store more gun shells—97 versus the 90 of the M4A1.

If the Sherman tank received a direct hit, its engine often would explode. This warranted it a few nicknames, such as “the Burning Grave” or “Tommy Cooker.” This created a distrust in the gasoline-driven M4 as opposed to its diesel counterparts. Further research determined that the propellant charges for the

ammunition were the problem. It was found that red-hot enemy projectiles that pierced the turreted gun ignited the propulsion charges, causing a chain reaction of explosions, sometimes blowing the turreted gun off altogether. This was fixed quickly with additional armor to combat penetration of the turret, and the ammo once stored in the turret was moved down into the main hull, where large steel plates protected it.

The M4 was quickly modified into different variants for carrying different loads of weapons, all the way up to howitzers. New turrets were put in place, as were new engines, giving the tank more power to trek through mud and other obstacles. Furthermore, a new suspension system was added in 1944, allowing the tank to absorb more energy upon firing weapons and from the impact of shells on its armor. This improved the longevity of the tank.

The M4 Sherman tank was first used by the British at the Second Battle of El Alamein in October of its production year. A month later, the Americans used the M4 at Operation Torch landings, the invasion of North Africa. Antitank teams of the Axis forces downed many a tank in the European and African theaters. The M4 had a better time dealing with the Japanese antitank teams in the Pacific theater, as their weapons were less devastating.

Production of the M4 Sherman tank continued after the end of World War II, and so a plethora of tanks was ready when the Korean War broke out. But more efficient tanks had been developed by this time, so the M4 took a back seat to the new developments and acted as a second line of defense during the war. Once the war was over, the M4 was used as a basis to develop the improved M46 and 47 Patton, which would eventually replace the M4, which was retired in 1957.

Manhattan Project

World War II brought many horrors of war the likes of which had never been seen before. Some occurred because of the scientific research and development intended to assist with the war effort, including the Manhattan Project, which designed and constructed the world's first-ever nuclear weapon.

The Manhattan Project was officially established in 1942 by the U.S. Army, though it had essentially begun in 1939. At its start, the project's funding was only \$6,000 annually, but by the end of it, it had cost an estimated \$2 billion, not accounting for inflation. The Manhattan Project had also employed up to 130,000 by the end of its operation. The project gained most of its traction when it was discovered that German scientists were working on similar projects involving nuclear fission, which set a tone of extreme urgency for the United States to compete.

By 1943, the U.S. government was cooperating with Canada and England on the effort, and the Manhattan Project remained active until it was disbanded on August 15, 1947, having been partially replaced by the U.S. Atomic Energy Commission.

Prior to the creation of the project, two Hungarian physicists, Leo Szilard and Eugene Wigner, drafted a letter expressing concern that the Axis forces were developing an extremely dangerous new bomb. President Franklin D. Roosevelt then set in motion the gathering of nuclear material and invested in the nuclear research of Enrico Fermi. The S-1 Committee, which considered the letter's concerns, met in October 1939 and concluded that uranium could yield some of the most destructive weapons the world had ever seen. In December 1941, after the attack on Pearl Harbor, the S-1 Committee met again. War was declared upon the Axis forces.

The key nuclear fissile materials for the bomb project were uranium-235, uranium-238, and plutonium-239. U-235 had to be separated from the more plentiful U-238. Robert Oppenheimer worked with Robert Serber to examine the neutron diffusion and hydrodynamics of the expected explosion. Italian physicist Enrico Fermi, who had come to the United States in 1938 to avoid discrimination against his Jewish wife, met with Oppenheimer and other leading theoretical physicists in the summer of 1942 to discuss the

theoretical possibility of the fission bomb. Oppenheimer assumed the role of director for the Los Alamos Laboratory where design concepts for the bomb were being developed.

As the Manhattan Project grew, so did the size and workload of the Los Alamos Laboratory. After years of testing designs for the weapon, Oppenheimer finalized one in early 1945. With the culmination of the project's work nearing, an interim committee was created to advise about future wartime and postwar use of nuclear energy.

The infamous first test of the bomb was known as Trinity and was executed on July 16, 1945, at an airbase about 100 miles south of Albuquerque, New Mexico. The bomb was set on the top of a steel tower and was observed by scientists and dignitaries alike from several bunkers many miles away. The news of the weapon's functionality was then given to President Truman at the Potsdam Conference in Germany, where he then told Stalin of the newfound superweapon. Truman authorized the use of the bomb just as the Japanese rejected the Potsdam Declaration, allowing the horrific act to be set in motion.

Only a few days later, the superweapons known as "Little Boy" and "Fat Man" were dropped upon Hiroshima and Nagasaki respectively. Upon the enactment of the nuclear attacks, the Manhattan Project had achieved completion of its sole objective and would soon disband.

Mead, Margaret (1901–1978)

Among the world's most renowned cultural anthropologists, Margaret Mead was a perceptive commentator on a wide range of world cultures, including that of the United States. Like her mentor, American anthropologist Ruth Benedict (1887–1948), Mead wrote for the layperson as well as for scholars. In this sense, she was a public intellectual. She was to cultural anthropology what British anthropologist Louis S. B. Leakey (1903–1972) was to physical anthropology: an accomplished scholar of worldwide fame. Throughout her career, Mead addressed myriad topics: nuclear energy, abortion, breastfeeding, civil disobedience, euthanasia, and premarital sex. In her eagerness to address the layperson, Mead wrote a monthly column for *Redbook* from 1965 until her death in 1978. Mead also addressed the public through radio, television, and cinema. She could be controversial, as when she advocated for the legalization of marijuana. Her popularity and her gender seem to have caused some anthropologists to resent her.

The oldest of five children, Margaret Mead was born December 16, 1901, in Philadelphia, Pennsylvania, to Edward Sherwood and Emily Fogg Mead, both distinguished academics. Though her parents were agnostic, Mead at age 11 sought baptism in the Episcopal Church and seems to have remained devout throughout her life. Mead attended DePauw University for one year before transferring to elite Barnard College in New York City. There she became engaged to theology student Luther Cressman. Declaring a major in psychology, Mead took an anthropology course in her senior year and met American anthropologists Franz Boas (1858–1942) and Ruth Benedict (1887–1948). Under Benedict's influence, Mead decided to pursue a career in anthropology. Mead graduated from Barnard College and married Cressman in 1923, next pursuing a master's degree in psychology at Columbia University. Boas encouraged Mead, like Benedict, to study Native American cultures, but Mead chose Samoa, a Polynesian island, where she began fieldwork on female adolescence in 1925. Mead's research led to the publication of *Coming of Age in Samoa*, where she cataloged Samoan women's frank promiscuity and lack of guilt about sex.

Cultural anthropologist Margaret Mead studied Pacific Islanders and, unlike those before her, resisted applying Western values to non-Western people. Her work suggested that Western standards about sex, gender roles, and child rearing were not natural, but culturally constructed. (Library of Congress)

From her research, Mead believed that culture determined people's ideas about women and, by extension, about men. Later investigators found that Samoans had "hoaxed" Mead by lying to her about their sexual practices.

Returning to New York City, Mead became assistant curator of ethnology at the American Museum of Natural History. In 1929, she earned her PhD in anthropology from Columbia University. Despite her duties, Mead took occasional leaves of absence to teach at Yale University, Vassar College, New York University, Emory University, and Columbia University. Mead sought to promote interdisciplinary studies in education, social work, psychology, sociology, psychiatry, and pediatrics. In the 1930s, Mead broadened her research to New Guinea, where she focused on

children, and to Native American cultures, where she studied gender issues, again arguing that culture, not biology, shapes gender roles. Hard-line hereditarians disagreed with Mead, seeing biology as the determinant of sex roles. During these years, Mead had several lovers. Because she was bisexual, some of her liaisons were with women. With her third husband, Mead had a daughter, her only child.

During World War II, Mead arranged a leave of absence from the museum to become executive secretary of the National Research Council Committee on Food Habits. The fact that the United States might have to ration food during the war gave Mead's assignment special urgency.

As she aged, Mead spent less time in the field, but her work continued to influence American culture.

Mead's examinations of the sexual habits of a number of cultures informed many Americans' ideas about sex during the counterculture of the 1960s. Second-wave feminists disagreed about Mead. Some women saw in Mead a powerful role model, while others, notably Betty Friedan (1921–2006), argued that the inaccuracy of Mead's early work had done women a great disservice.

Her awards included 28 honorary degrees from universities worldwide, the Viking Medal in anthropology, and the Presidential Medal of Honor. During her lifetime, she presided over the American Anthropological Association, the American Academy for the Advancement of Science, the World Federation of Mental Health, and the Society for Applied Anthropology. She published 44 books, 18 of them coauthored, and more than 1,000 articles and reviews. In 1978, the *World Almanac* named her one of the world's 25 most influential women. The Library of Congress holds her papers. Margaret Mead died November 15, 1978.

Microwave Oven

Microwave ovens are appliances now found in almost every American household. They are popular because they are so convenient, heating food quickly by using thermal energy.

Microwave technology is attributed to physicist Percy Spencer (1894–1969). Spencer discovered the power of microwaves accidentally: he was testing a magnetron when he noticed that a chocolate bar in his pocket had melted. He realized that the magnetron was

emitting microwaves capable of heating food. This led him to create the “Radarange” in 1946, a refrigerator-sized metal box into which a magnetron would send microwaves to heat food. The first Radaranges cost several thousand dollars and were used primarily by commercial kitchens. By the 1950s, smaller Radaranges were developed for home use but cost upward of \$1,295, more than most American families could afford.

In the 1970s, improvements in magnetron technology led to smaller, cheaper-to-manufacture microwave ovens. This trend has continued, and today, many consider microwaves essential kitchen appliances.

Military Technology (World War II)

While wars are waged on the battlefield, in the skies, or on the waves, they are often won or lost on drawing boards, proving grounds, or in laboratories. Technology, whether in the form of high-energy foods or nuclear power, can spell the difference between military victory and defeat. The military technologies developed during World War II were no exception. Although some were improvements over World War I technologies, other innovations during the later conflict were made to counteract those being deployed by one side or another. By 1945, military technology had become the signature of World War II, so much so that it became known as the first war where military operations widely targeted enemy research efforts. It was also a struggle in which scientists, physicists, mathematicians, and engineers became commodities, leading one observer to conclude that the Allied victory over fascism had been a result of the quality of the scientific community that each side possessed. In an arena in

which measures and countermeasures followed hard on each other's heels and where change was the only constant, World War II truly gave new meaning to Plato's assertion that necessity is the mother of invention.

Advancements in weapons clearly demonstrated just how much of an impact technology would have on World War II. Nothing was left untouched, from the weapons that men carried into combat to the devices that would carry men into combat. Semiautomatic weapons gave way to portable, fully automatic ones. Open-cockpit aircraft were eventually replaced by sleeker, more aerodynamic, canopied models. Bombers would, by war's end, employ technology that would allow them to fly farther, be less vulnerable to attack, and deliver their payloads more accurately. Even battleships, which had been the gold standard in naval warfare during World War I, had by 1945 been neutralized and perhaps even rendered obsolete by the advent of aircraft carriers. The battleship's earlier nemesis, the submarine, had already been partially defanged by sonar, a military technology that used sound waves to seek out and help destroy them.

For every technological measure introduced during World War II to help one side or the other turn the tide, there was a response waiting just around the corner to stem it. German tanks terrorized Allied forces during the war, but once the United States and Britain began building and deploying tank destroyers that fired armor-piercing shells, tanks became vulnerable. As aerial bombardment became more effective, new responses on that front were deployed. Radar, an acronym for "radio detection and ranging" technology, helped spot aircraft. Once radar had fixed an enemy plane's location and altitude, antiaircraft artillery would be trained on the target, firing radar-directed proximity-fuse shells. They didn't have to achieve a direct hit; the shells just had to get high enough and close enough to detonate, and they let the exploding shrapnel do the rest. To escape antiaircraft fire, planes had to increase altitude, and this meant that crew members risked oxygen deprivation until cabins could be pressurized. The altitude also meant that bombing accuracy was jeopardized until more accurate targeting technologies, such as the Norden bombsight, were developed. Of course, military technology was showing signs that human involvement in war might soon be passé. Ordnance that

reduced human involvement began to appear during the latter stages of the conflict. Germany produced the first generation of smart bombs followed by the V-1, the world's first cruise missile, and later the V-2, the first ballistic missile weapon. On a more modest, yet equally lethal level, precision-guided munitions such as magnetic torpedoes and aiming devices for machine guns using special-purpose mechanical and electronic digital systems would further distance humans from harm's way. Of course, the ultimate technology that drew a line in the sand separating some humans from war was atomic power. The invention of the atomic bomb meant that a single aircraft could carry a weapon sufficiently powerful to devastate entire cities. The aftermath of the atomic bombings of Hiroshima and Nagasaki meant an end to World War II—and an end to any doubts about technology's role in conflict.

But military technology during World War II wasn't all about bombs and bullets. Armies needed to eat to fight, so dieticians were enlisted to help find the vitamins and minerals that a body needed to stay healthy and cope under stressful situations. Studies were commissioned to find out how many calories were consumed during combat training, and theories were constructed about how many more calories a man might need in actual combat. The food a soldier carried was designed to give him the most nutrition and energy while still managing to taste good. C Rations provided a number of meat dishes and desserts. D Rations, typically used in emergencies, were small, high-calorie, high-energy chocolate bars. The army said it couldn't taste too good for fear that soldiers would eat them instead of saving them for a more appropriate time. So the chocolate that soldiers carried was designed by science to be good but not tasty. M&M's just tasted good. The chocolate candy, which, as most people know, "melts in your mouth and not in your hand," was the result of a collaboration between the Mars and Hershey candy companies. The beady chocolates were sold to the military when the United States entered World War II and were used as an easy way to provide troops with chocolate on the battlefield.

Military technology also ventured into the realm of medical technology. While penicillin had been invented before the war, the technology to mass-produce it came into existence during the fighting,

which made it available to millions of people around the world. Medicines against diseases like malaria also became critical for the United States in its fights in tropical climates like the South Pacific. Pesticides like DDT played an equally critical role in killing mosquitoes. And there was more evidence of military technology influencing not only the way the war was fought but even the lives of civilians.

Plastic wrap, known to some by the trademarked name “Saran Wrap,” became a substitute for aluminum foil for covering food. Cardboard milk and juice containers replaced glass bottles, and plywood emerged as a substitute for scarce metals and was used for everything from the hulls of PT boats to aircraft wings. Speaking of aircraft, pilots who had to bail out of their damaged planes no longer “hit the silk,” a term used to describe the deployment of a parachute. Japan’s occupation of the silk-producing regions of Asia sent scientists scurrying to find a replacement. The answer was nylon, a synthetic fiber that would soon show up in automobile tires, since the war had also cut off America’s access to rubber. Coincidentally, nylon also began showing up on the legs of American women. Deprived of silk stockings, they had resorted to shading their legs with makeup and drawing lines up the backs of their legs to complete the illusion that they were wearing seamed stockings. Nylon hosiery saved the day, not to mention the American woman’s sense of fashion under adverse conditions.

Some have referred to World War II as the first total war and the first high-tech war. Jet planes, radar, sonar, and DDT, to mention but a few, were all technological devices designed for waging war. Many of those innovations found uses after the shooting stopped. DDT’s uses in peacetime proved environmentally disastrous. But not everyone immediately connects the rise of computers to the war effort. The reality is that many of society’s most significant technological achievements were made in the midst of one of society’s most destructive events. But if necessity is indeed the mother of invention, then war has had to figure greatly in that process.

MIT Radiation Laboratory

The MIT Radiation Laboratory, also known as “Rad Lab,” was an independent laboratory at the Massachusetts Institute of Technology (MIT) in Cambridge, Massachusetts, staffed by civilian and academic scientists from every discipline and operated from October 1940 until December 1945. It played a crucial role in U.S. military research and development during World War II, especially in developing the microwave radar (radio detection and ranging) system.

Before World War II, a practical application of microwave radar had not been developed. The British government requested help from the U.S. National Defense Research Committee (NDRC) to develop this proficiency. President Franklin Roosevelt approved the research, and the project commenced. The Rad Lab developed the first worldwide radio navigation system called Loran-A (or Loomis Radio Navigation, a.k.a. “LRN”) and was responsible for developing most of the microwave radar technology used by the United States during World War II.

Radar works by transmitting electromagnetic waves and analyzing the reflecting echo off an object. Since the discovery of radar, it has found many uses, such as detection and identification of objects’ velocity, range, and direction. But it was not until a scientist invented an oscillator that using radar to detect objects from airplanes many miles away was possible in World War II. The British government focused on developing practical applications for airborne microwave radar in

response to the threats and impact of German drones and submarines. It had had no way of detecting German V-1 drones and German U-boats from a distance.

In 1940, before the United States entered World War II, Britain partnered with the NDRC to develop microwave radar systems. Vannevar Bush, the scientific advisor to President Franklin Roosevelt and head of the U.S. Office of Scientific Research and Development (OSRD), worked with his colleague, Karl Compton, the president of MIT, and James Conant, president of Harvard, to create a plan to present to President Franklin Roosevelt for the NDRC to do this. Roosevelt quickly approved, since he felt this would help the Allied forces to win the war.

Karl Compton led the council's oversight of technologies that could detect objects from a distance. The task was quickly narrowed to detection using microwave, with Alfred Loomis, a wealthy American scientist and head of the NDRC Microwave Committee, developing a device. Loomis's committee's promising results found that microwaves could theoretically work. In October 1940, Compton and Loomis selected MIT as the site of the radiation laboratory that would build magnetrons and research microwave electronics. The Rad Lab officially opened in November 1940 as the approved joint effort between U.S. and British scientists.

During World War II, most air and naval combat was fought with radar in the UHF range and below. Following the attack on Pearl Harbor and the entry of the United States into the war, the work at Rad Lab expanded, focusing research on physical electronics, microwave physics, electromagnetic properties of matter, and microwave communication principles. One of the most notable microwave radars that the lab developed was the SCR-584, a widely used gunfire control system. It was first used in combat early in 1944 on the Anzio beachhead in Italy. This radar caught the Germans unprepared.

The MIT Rad Lab closed operations in December 1945. It had employed more than 4,000 people working on several continents and had spent close to \$4 million per month. It had industrialized over 100 radar systems, and its designs resulted in \$1.5 billion of radar production in industry. Its innovations, organization, and equipment contributed to the creation of MIT's Research Laboratory of Electronics (RLE).

During the five years of its operations, the MIT Radiation Laboratory made significant contributions to development of microwave radar technology in support of the war effort. Its inventions included the H2X radar used for aiming bombs, a shipboard search radar, harbor and coastal defense radars, gun-laying radars, ground-controlled approach radars for aircraft blind landings, interrogate-friend-or-foe beacon systems, and the long-range navigation (loran) system.

Some of the most critical contributions of the MIT Radiation Laboratory were the microwave early-warning (MEW) radars, which effectively nullified the German V-1 drone threat to London, and air-to-surface vessel (ASV) radars, which turned the tide on the German U-boat threat to Allied shipping. Aircraft equipped with ASV radars destroyed a total of 25 German U-boats. The fundamental contributions to the design and deployment of microwave radar systems played a decisive role in the Allied victory. All of the people who worked there made very important and lasting contributions to microwave theory and technology, operational radar, systems engineering, long-range navigation, and control equipment in the United States.

Neoprene

Neoprene (chloroprene) is a commonly used synthetic rubber with elasticity as opposed to rigidity in its resin. Elmer Keiser Bolton first developed the

chemical. He was the research director at DuPont at the time. Using the research of chemists before him, he aimed to polymerize the brittle versions of existing acetylene plastics. Hydrogen chloride gas and monovinyl acetylene reacted to form chloroprene, which, when left to sit polymerized into polychloroprene.

This substance was found to bounce when dropped, and it was resistant to UV radiation that caused the degradation of most plastics. It was then renamed Duprene, since it had been developed at DuPont; later, it was renamed to “neoprene.” Neoprene is most commonly used in wet suits. The low density of the structure makes it light and helps it maintain pliability in direct sunlight. Some other common uses today are in laptop sleeves and Halloween masks.

Plastics have a negative effect on the environment, and neoprene is not exempt from this. Weather balloons are made from neoprene, and they can pop at altitude, landing in bodies of water or elsewhere. Since neoprene was developed to resist degradation, it remains as pollution for years before it begins to degrade. Animals may ingest it, which can have devastating effects on their health.

Nuclear Weapons. See Atomic Bombs/
Nuclear Weapons

Oppenheimer, J. Robert (1904–1967)

J. Robert Oppenheimer was a pioneer of American theoretical physics, significant for his research in the areas of astrophysics, spectroscopy, and quantum field theory. He is primarily remembered as the “father” of the atomic bomb. As the head of the Manhattan Project, he helped develop the world’s first nuclear weapon in 1945.

Born in New York City in 1904, Oppenheimer grew up in a well-to-do family. His father was a

successful German textile importer, and his mother was an artist. The family was Jewish but religiously nonobservant.

Oppenheimer studied physics at Harvard and graduated *summa cum laude* in 1922, having completed his degree in three years. He was then accepted at Cambridge to work in the Cavendish Laboratory, a placement that confirmed his suitability for theoretical rather than experimental physics. In 1926, Oppenheimer left Cambridge to study under Max Born at the University of Göttingen, developing the Born-Oppenheimer approximation, the assumption that the motions of atomic nuclei and electrons in a molecule can be separated. He received his PhD in physics in 1927. Oppenheimer then embarked on teaching, serving concurrently on the faculties of the University of California, Berkeley and the California Institute of Technology beginning in 1928.

In 1942, Oppenheimer was invited to be part of the Manhattan Project, the secret program tasked with actualizing the newly developed fission process involving uranium-235 into a nuclear weapon. He initially was assigned to work on fast neutron calculations, and he brought together a group of his own students and European physicists to UC Berkeley for a crash course in bomb theory. Later in the year, Oppenheimer was appointed the scientific director of the Manhattan Project’s secret weapons laboratory. He had a key role in the selection of the site for the centralized secret research laboratory at Los Alamos, New Mexico. After three years of development and refinement, the atomic bomb was tested on July 16, 1945, in the first artificial nuclear explosion that took place near Alamogordo, New Mexico, a site that was codenamed “Trinity.” Soon after this test, an atomic bomb was dropped on the Japanese city of Hiroshima, which Oppenheimer viewed as a triumph. However, the subsequent bombing of Nagasaki did not meet with Oppenheimer’s approval, because he did not feel that this bombing was militarily necessary. Oppenheimer resigned from the Manhattan Project later that year after witnessing the destruction caused by the atomic bomb. He was awarded the Medal for Merit for his role as director of Los Alamos by President Harry S. Truman in 1946.

From 1947 to 1952, Oppenheimer served as the chairman of the General Advisory Committee to the

Atomic Energy Commission, during which time he advocated for international arms control. Oppenheimer voiced his opposition to the development of the hydrogen bomb in 1949, a stance that was politically fraught and which may have led to accusations of his being a communist. Due to suspicions of his being sympathetic to the communist cause, Oppenheimer's security clearance was revoked in 1953. In 1963, President Lyndon B. Johnson presented him with the Atomic Energy Commission's Enrico Fermi Award, an award perhaps bestowed in an attempt to compensate for this affront.

From 1947 to 1966, Oppenheimer served as director of Princeton's Institute for Advanced Study in Princeton, New Jersey. The mission of this Institute was to bring together academics from multiple disciplines to solve the world's pressing issues. During this time, Oppenheimer focused on research in quantum and relativistic physics.

In 1960, motivated by what he saw as the growing danger to humanity that could result from scientific discoveries, Oppenheimer founded the World Academy of Art and Science with Albert Einstein, Bertrand Russell, and Joseph Rotblat. Oppenheimer died of throat cancer in 1967.

Paul, Les (1915–2009)

Les Paul was a guitarist and inventor who pioneered multitrack sound recording. Lester Polfuss was born on June 9, 1915, in Waukesha, Wisconsin. An inveterate tinkerer throughout his life, Les Paul amplified his guitar as a youngster by sticking a phonograph needle into it attached to a radio speaker. After starting out in country music as "Red Hot Red" and "Rhubarb Red,"

he established himself as a jazz performer in the 1930s under the name Les Paul. He performed with some of the biggest names of the day, both as a soloist and with his trio, including Fred Waring's Pennsylvanians, the Andrews Sisters, and Bing Crosby, with whom he was featured on the number-one hit single, "It's Been a Long, Long Time" (1945).

Paul worked hard to improve the sound of both his instrument and his recordings. Acoustic guitars lacked the volume to solo alongside brass instruments, so magnetic pickups were added to amplify them. Paul made his own pickups and used electrified archtops, which he referred to as "clunkers," but vibrations from their hollow bodies interfered with vibrations from the strings. Believing that a solid-body guitar would eliminate the distortions, Paul designed "the Log" in 1941, which was a four-by-four-inch block of wood to which he attached a Gibson neck, an Epiphone fretboard, and two pickups. He then added two halves of an Epiphone guitar to the block so it looked like a traditional guitar. Neither Gibson nor Epiphone were interested in manufacturing it.

Paul built a recording studio in his garage and began to experiment with multitrack recording (which he called "sound on sound"), which was painstakingly done on wax disks by playing along with one disk while recording onto a second one. He also used delay, echo, close miking, reverb, phasing, and flanging. Paul's "new sound" debuted on the song "Lover" (1948), which featured his overdubbed electric guitar on multiple parts, some of which were recorded and played back at different speeds. After Crosby gave him an early Ampex tape recorder, Paul immediately added a fourth head, which enabled him and second wife Mary Ford to play and sing along with what had been recorded on the first take as it was recorded as a new track on the same tape.

This also enabled them to make recordings away from their studio. Paul later was involved with Ampex in the development of the first eight-track recording system. The couple had 28 hits between 1950 and 1957, including "How High the Moon" and "Vaya con Dios," all of which featured overdubbing of Paul's guitar and Ford's voice, making it sound like they were accompanied by an ensemble. They also produced their own television show from 1953 to 1960. To recreate their multitracked songs in live performances,

Blues guitarist and luthier Les Paul is famous for his innovations in solid body electric guitars, recording technology, and playing style. He is the only person in both the Inventor's Hall of Fame and the Rock and Roll Hall of Fame. (Library of Congress)

Paul built a device he named the “Les Paulverizer” to control backstage tape equipment from onstage.

The success of the Fender Telecaster convinced Gibson to manufacture a solid-body guitar, and they brought a prototype to Paul for his endorsement. The Gibson Les Paul was released in 1952, and it would become a favorite of many rock musicians. Ironically, Paul and Ford's recordings became less popular as music tastes changed and young people embraced rock 'n' roll, which was based on the electric guitar that Paul had long championed.

Among Paul's many honors were three Grammy Awards (1977, 2006), a Grammy Trustees Award (1983), the James Smithson Bicentennial Medal (1996), a Grammy Technical award (2002), the Emmy Lifetime Achievement Award (2004), the Sammy Cahn Lifetime Achievement Award from the Songwriters

Hall of Fame (2005), and the National Medal of Arts (2007). Paul and Ford's recording of “How High the Moon” was inducted into the Grammy Hall of Fame (1979), and Paul was inducted into the Rock and Roll Hall of Fame (1988), the National Inventors Hall of Fame (2005), and the Broadcasting Hall of Fame (2006). He died on August 13, 2009, at age 94.

Penicillin

Penicillin is an antibiotic that can bring a wide range of bacterial infections under control within a relatively short time. Before its discovery, medical treatments for infections were ineffective and dangerous. Alexander Fleming (1881–1955) discovered the antibiotic properties of a penicillium spore due to an unintended petri dish contamination. Howard Florey (1896–1968), Ernst Chain (1906–1979), and their team of researchers turned Fleming's lab accident into a life-saving drug. During World War II (1939–1945), Allied leaders expedited the mass production of penicillin to make it available for the treatment of wounded troops. After the war, penicillin was made available to the civilian population. Since that time, researchers have expanded the number of available antibiotics based on penicillin's chemical composition. Although penicillin has some drawbacks, it has revolutionized modern medicine and saved many lives.

In ancient times, doctors used maggot therapy to treat flesh wounds. As maggots fed on dying flesh, they excreted antibacterial substances that helped fight infection. However, these doctors had no effective tools against internal infections. In the 18th and 19th centuries, doctors often treated patients with internal infections with laxatives or by bleeding them with the aim of flushing out body toxins. Both treatments often made matters worse. Since the Middle Ages, doctors used toxins to reduce the symptoms of syphilis, but there was no known cure.

In the 1930s, German doctors used sulfa drugs to reduce bacterial infections. Unfortunately, many patients experienced side effects from sulfa drugs ranging from rashes to kidney failure. In 1929, Fleming was working on a routine bacteriology experiment at St. Mary's Hospital in London. While sorting through some petri dishes, he noticed that a dish bearing colonies of staphylococcus was growing a stray mold, which had contaminated the dish by accident. After further experimentation, he noticed that the mold was able to kill bacteria. Fleming, who was awarded the Nobel Prize in 1945 for his discovery, had no interest in investigating its medical benefits.

In 1939, Florey, Chain, and their team of researchers at Oxford University made penicillin available to

the pharmaceutical industries in both Great Britain and the United States during the same year that World War II broke out in Europe. As a consequence, the life-saving drug remained in Allied hands during the war while the Axis powers had to do without it. According to historians, penicillin saved many Allied lives and may have ultimately contributed to Allied victory.

After the war, civilians enjoyed the benefits of penicillin, which was regarded as a miracle drug due to its dramatic results. The astounding benefits of penicillin encouraged scientists to conduct future research with molds, and they developed various antibiotics that could treat different bacterial infections. Since some people are allergic to certain drugs, the availability of different drug choices is beneficial.

Once researchers isolated the antibacterial chemical components in penicillin, they were able to create a semisynthetic version of penicillin in 1957. Semisynthetic penicillin is much more effective than naturally occurring penicillin, because it is more resistant to breakdown when in contact with gastric acids in the stomach. However, all penicillin-related drugs have two major shortcomings. First, penicillin cannot cure virus-related illnesses such as the common cold. Although proven vaccines for some virus-related illnesses exist, in most cases, people must combat life-threatening virus-related illnesses with nothing but their own immune systems. Second, bacteria can mutate and become resistant to antibiotics.

For this reason, doctors must exercise caution in prescribing penicillin, because overuse is the biggest factor that leads to resistance. If bacteria mutations should outpace available drugs, the world will once again be at the mercy of bacterial infection as it was before the discovery of penicillin. Additionally, antibiotics have had an undesirable side effect on hospital environments. In some fatal cases, resistant bacteria have attacked patients with compromised immunities. In spite of these drawbacks, penicillin has remained invaluable. Approximately 45,000 tons of penicillin-related antibiotics are produced worldwide every year. Compared to medical options in previous centuries, the discovery of penicillin was a tremendous technological leap forward.

pH Meter

The pH meter is a scientific invention that measures the acidity or alkalinity in water-based solutions. The pH meter was created in October 1934 by American inventor Arnold Orville Beckman. Beckman is credited with registering the first patent on a complete chemical apparatus for the measurement of pH, which he originally named the “acidimeter.”

The pH meter generally consists of a voltmeter (an instrument used to measure electric potential in volts) attached to a pH-responsive electrode and a reference electrode (this is unvarying for reference). The voltmeter measures the electric potential when the electrodes are placed inside the solution, acting as a battery since the two electrodes need a medium to run current between the two electrodes to determine the acidity or alkalinity on the pH scale of 0 to 14.

PH meters can be as simple as pen-like devices or a complex piece of machinery that can refine the accuracy of the measurements, including temperature and volume. PH meters now also come with solid-state electrodes in lieu of conventional liquid-state electrodes to use in soil or other mediums.

Photocopier

A photocopier is a machine that makes paper copies of documents and other visual images in an efficient manner and is a tool widely used in the business, education, and government sectors.

In 1881, the earliest version of the photocopier was invented by David Gestetner. It used a Gestetner stencil duplicator, a type of early duplicating machine. It was not until 1938 that the next version of the photocopier was introduced by inventor Chester Carlson. Carlson’s innovations in electrophotography led him to a working copy machine that did not require chemicals or special paper.

In 1959, the photocopier began to use a technological technique known as the xerographic copying process, which works on the basis of electrostatic charges. The xerography process is the dominant method of reproducing images and printing computer data used in photocopiers and also in similar machines, such as laser printers and fax machines. The first xerographic photocopier to hit the market was in 1959, the same year that this copying technique was introduced. In 1968, the Color-in-Color copier appeared, allowing photocopiers to print copies in the same colors as the original. It uses a method known as the dye-sublimation process. The first electrostatic color copier was released by Canon in 1973.

The photocopier has several steps to its functions. To begin, a high-voltage wire known as a “corona wire” gives an electrostatic charge to the surface of the drum, which is coated with a semiconductor material such as selenium or germanium. The light is beamed in thin strips onto the original image, but the light is reflected only by the white areas of the picture. The light then hits the drum, which is specially conditioned to be photoconductive, meaning that the drum neutralizes the positive charges when the light hits it. With the positive charges neutralized, the white areas of the picture become neutral while the black areas are positive. When the negatively charged toner is applied to the drum, it sticks to the positively charged areas. The toner is then attracted to a positively charged piece of paper. The toner is a dry ink substance that is heated to make it melt and to bind it on the piece of paper.

With the technological and digital advancements in scanning and the use of smartphone cameras in the 21st century, it has been predicted that our reliance on photocopiers will decrease. However, higher-end photocopiers are capable of producing color, heavy-duty cycles, and large-format printing, which are in high demand at print and design shops. An array of

photocopier models are available from six major photocopier manufacturers: Brother, Canon, Konica Minolta, Ricoh, Sharp, and Xerox. All copies are often nicknamed “xeroxes,” as Xerox was the first company to mass provide copiers to businesses.

Pinball and Arcade Games

Arcade games are coin-operated gaming machines typically found in areas frequented by the general public. One of the first of these machines, which popularized arcade games worldwide, was the pinball machine. Over the years, technological advancements have added dimensions of sound, visuals, and score-keeping to enhance the gaming experience, as well as elements of skill required of players. Arcade games gave rise to the current phenomenon of home- and computer-based personal video game consoles.

Originating before the late 1700s, the earliest form of what is now known as pinball was played in France by Louis XIV, where players would shoot balls with a cue from one end and knock down wooden pins on the other. In 1869, a spring launcher was added to the game. This set the foundation for the modern iteration of pinball. The objective of pinball is to score as many points as possible by striking various targets on the pinball play field. The player attempts to score the most points without allowing the ball to fall into the drain and uses “flippers” to help keep the pinball in play. The game ends when all of the pinballs have fallen into the drain.

In the 1930s, the rise of electricity brought major advances to the design of the pinball machine and

added the ability to track the player’s score. In 1947, player-controlled flippers were introduced that allowed the player to attempt to keep the ball in play for longer. Advanced electronic components and digital displays were introduced in the 1970s, which allowed for the introduction of a story element to games. These advancements revolutionized the objectives of pinball, as players now had to hit certain targets to progress the game as it followed the story. Unfortunately, just as these major technological advancements encouraged the gameplay of pinball to new heights, they also brought along new possibilities in arcade games. In the 1980s, the popularity of pinball began to be replaced rapidly by a growing adoration for arcade video games.

Arcade video games boomed in the 1980s, and major games such as *Pac-Man*, *Space Invaders*, and *Galaga* were placed in video arcades across the world, often replacing rows of pinball machines. Arcade video games became so popular that they often showed up in restaurants or bars, and the industry was worth \$8 billion in 1981. Arcade video games added skill elements that stood in contrast with the limited movements allowed in pinball. In games such as *Donkey Kong* and *Space Invaders*, the success of the player was based mostly on the timing of the player’s movements. Culturally speaking, arcade video games sparked a massive interest in video games. In particular, *Pac-Man* generated so much popularity that the buzz surrounding it became known as “Pac-Mania,” and it was even acknowledged by then-U.S. president Ronald Reagan.

Although the rise of arcade video games had been assisted by the arrival of new technological advancements in gaming, it also saw a fall in popularity for the same reason. In the late 1980s, the golden age of arcade video games was coming to an end as new technology brought the invention of personal, home video game consoles. Rather than having to visit their favorite arcade to play video games, it was now possible for people to bring the video games to their homes.

In the 1990s, however, innovations in gameplay allowed for a small “renaissance” of arcade video games. New levels of competition were added so that a player could compete against a friend rather than against the machine. Fighting games such as *Street*

Fighter and *Mortal Kombat* immortalized these new forms of arcade video games. Pinball also enjoyed something of a comeback in the 1990s, as manufacturers had now perfected the use of technology to enhance the pinball gameplay. The two major pinball manufacturers included WMS Industries and Sega Pinball. They contributed to the new interest in pinball by including cultural references in the games. Popular films of the 1990s were licensed to be used in association with pinball machines, such as *The Addams Family*, *Star Trek: The Next Generation*, and an Indiana Jones–themed pinball machine that was aptly named *Indiana Jones: The Pinball Adventure*. However, even though these enhancements generated some interest for pinball in the 1990s, it wasn't enough to measure up to the growth of their video-based counterparts. By the end of the 1990s, WMS Industries had left the pinball industry, and Sega Pinball had sold its division to the sole manufacturer remaining: Stern Pinball.

The 2000s saw interest in arcade video games decline worldwide as personal video game consoles began to dominate the gaming industry. Although the major pinball manufacturers within the United States, such as WMS Industries, had exited the business in the decade prior, smaller, independent manufacturers began to appear and created pinball machines that can still be played today. Arcade video games also evolved from the early days of *Pac-Man* and *Galaga*. Interactive arcade video games in the 2000s included *Dance Dance Revolution* and sit-down vehicle racing games that allow the player to mimic driving a real vehicle. Today's arcade video game industry is small, yet adored. In many countries such as the United States and Japan in particular, arcades have remained popular and remain a major part of the culture.

Plastic Wrap

Plastic wrap, also known as “cling wrap,” “food wrap,” or “pliofilm,” was originally made from polyvinyl chloride (PVC) or polyvinylidene chloride (PVDC). Eugen Baumen synthesized PVC in 1872 and in 1926, B. F. Goodrich plasticized the compound for use in a variety of applications, including plastic wrap. Dow Chemical discovered PVDC in 1933 and marketed the product as Saran Wrap in 1949. Saran Wrap quickly became popular with Americans and remains widely used in food storage and preservation.

While the vast bulk of plastic wrap is used in food applications, the wrap is sometimes used as a packing material. It is also used in neonatal units, where premature infants are wrapped in the plastic to keep them warm.

Much of modern plastic wrap is still made from petroleum-based plastics, though many companies now make the wrap from more sustainable, vegetable-based bioplastics. Concerns about the interface between PVC and PVDC and food, particularly with the potential toxicity of plastic wrap, has also fueled the bioplastic industry.

Radar

Radio detection and ranging, or “radar,” technology depends upon the fact that radio waves reflect off metal. Christian Hülsmeyer, a German, first utilized the phenomenon to detect objects otherwise unseen. In the 1930s, a number of scientists worked to develop radar systems. Scientists working for the U.S. Navy created the first radar tube, which then allowed radar transmitters and antennas to accurately fix long-range targets. Scientists working for the navy developed a ring oscillator that increased radar power, while army personnel

developed more effective antennae for aircraft-based radar. In 1939, the federal government awarded RCA Corporation a contract to mass-produce long-range detection systems. RCA dubbed the technology “RADAR” in 1940. Radar is differentiated from sonar in that radar uses electromagnetic energy in the form of radio waves while sonar uses sound waves and the echo principle.

Hülsmeier first demonstrated a simple ship detection device for the German Navy in 1904. While it was helpful in detecting ships hidden in fog, it could only do so if the ships were nearby. During World War I, English inventors, responding to the rumor that Germany had a “death ray,” developed oscilloscopes to better display signals and better antennae for longer radar range.

Significant headway in radar technology came in the 1930s. In 1934, Robert M. Page, working for the navy, developed a radar device that could detect objects up to a mile away. Page also developed a duplexer that allowed one antenna to be used as both a transmitter and receiver and a ring oscillator that facilitated the use of multiple radar tubes and increased pulse signal. In 1939, the U.S. Navy installed Page’s improved radar system on the USS *California*, a battleship first launched in 1919 and sunk at Pearl Harbor in December 1941 and relaunched in March 1942. The U.S. Army developed and utilized radar technology for World War II bombers like the B-17 and others.

Radar has traditionally been used in military applications, though it was also used in civilian aviation after World War II as well as for weather prediction and mapping applications. Law enforcement personnel use radar guns—really handheld Doppler radar projection apparatuses—to detect the speed of automobiles.

Astronomers also use radar. The Arecibo Observatory in Puerto Rico, owned by the National Science Foundation (NSF), is the largest radio telescope in the world. The telescope collects information for the Search for Extraterrestrial Intelligence (SETI), collects military intelligence, and is used for other scientific research.

Refrigerator

Refrigeration is the process of removing heat from an enclosed space, or from a substance, to lower its temperature. A refrigerator uses the evaporation of a liquid to absorb heat. The liquid, or refrigerant, used in a refrigerator evaporates at an extremely low temperature, creating freezing temperatures inside the refrigerator. The year 1859 saw the invention of the first gas absorption refrigeration system using sulfur dioxide, a gaseous ammonia that dissolves in water, and methyl formate as refrigerants. These gases were widely used for that purpose until the late 1920s. These gases were replaced with safer compounds that compress and heat up, working to cool the inside air of the refrigerator.

In the 18th century, people cooled their food with ice and snow, either found locally or brought down from mountains. For centuries, people used large blocks of ice to keep food cold, and some only chilled food seasonally, taking advantage of cold ambient temperatures. In 1834, Oliver Evans, an American inventor, designed the first refrigeration machine. The first practical refrigerating machine was built by Jacob Perkins, the “Father of the Refrigerator.” In 1876, Carl von Linden, a German scientist, invented and patented the process of liquefying gas that is part of basic refrigeration technology. Ammonia, sulfur dioxide, and methyl formate compound were utilized as refrigerants. Fred W. Wolf invented the first refrigerators for kitchen appliance and domestic use in 1913.

Due to several fatal accidents that occurred due to the use of these gas compounds; three American corporations developed a less dangerous method of

refrigeration. Their efforts led to the discovery of Freon, but it, too, became a problem. Its chlorofluorocarbons deplete the ozone layer and have high global warming potential.

In the United States, the refrigerator became an essential piece of kitchen furniture. In the 1950s, over a million of them were manufactured. Mass production of modern refrigerators began in earnest after World War II. More than 80 percent of American farms and more than 90 percent of urban homes had one. New refrigerants were developed in the early 21st century that are safer for the environment, but their application has been held up due to concerns over toxicity and flammability.

Richter Scale

The earthquake magnitude scale, the Richter scale, named after its creator Charles Richter, is a numerical scale used on the recordings of seismographs. The scale measures the amount of energy that earthquakes release and establishes a numerical rating for that earthquake that describes its size. The more energy released, the higher the earthquake’s number on the scale.

In the 1930s, California Institute of Technology professor Charles F. Richter decided to create a system that would accurately measure seismic activity. He did some earthquake measuring tests in early 1932. In 1920, Richter had read Japanese seismologist Kiyoo Wadati’s paper on earthquake depths. Wadati, who worked at the Central Meteorological Observatory in

Japan, studied earthquakes and determined the connection between surface displacement and distance from quake epicenters.

Richter began to gather data from previous earthquakes in Japan and by measuring current quakes. He began plotting data on a numerical scale and further systematized it. His magnitude scale resembles the stellar magnitude scale used in astronomy to measure the brightness of an astronomical object as seen by an observer on earth. It wasn’t until 1978 that this magnitude scale used to rank earthquake was referred to as the Richter scale.

Richter based his measuring system on logarithmic equations that could tell what the size of an earthquake was. In the 1930s, there was no reliable system in place that could interpret seismic activity data as a quantitative scale. In its early stages, the Richter scale was unable to measure smaller earthquakes or aftershocks because seismic instrumentation was not yet sensitive enough. It also could not characterize earthquakes of similar measurements as different types. Seismologists later discovered that earthquakes vary in the direction of vibration, so despite them having the same numerical readings, the destruction caused by high-level earthquakes is not the same. With further development, the Richter scale became the standard for measuring earthquakes.

Rocketry (Pre–Space Age)

Any vehicle, from missiles to aircraft, that propels itself with a rocket engine is considered a rocket. Rocket engines create thrust with propellant self-contained in

Robert H. Goddard is the father of American rocketry. His theories on spaceflight, while considered ridiculous in the early 20th century, have now been proven accurate. (Library of Congress)

the engine, which, when expelled, causes forward movement in the opposite direction of the exhaust. Robert H. Goddard created the world's first liquid-fueled rocket in 1926. The science of rocketry has had to overcome several problems, including engine and thrust mechanics, the effect of gravity (both earth and celestial) on rockets, the drag that rockets create and, for rocket-powered aircraft, problems of lift.

For most of world history, space exploration and travel only existed in fiction. For example, Jules Verne's (1828–1905) *De la terre à la lune* (*From Earth to the Moon*) and *Autour de la lune* (*Around the Moon*) from the 1850s explored the theory of space travel. His novels brought the idea to the masses. Based on theoretical scientific work, Verne wrote vivid descriptions of the moon and details of how outer space was vastly different from Earth.

The father of cosmonautics, Konstantin Tsiolkovsky (1857–1935), credited Jules Verne's novel *From Earth to the Moon* for his curiosity about the distance of traveling to the moon. Tsiolkovsky researched ideas for steering thrusters, space stations, and airlocks for exiting a spaceship into the vacuum of space, as well as closed-cycle biological systems to provide food and oxygen for space colonies. Tsiolkovsky's contributions to rocketry were formally recognized in 1921.

Scientists working in early 20th-century rocketry research were mainly concerned with exploring new ways to construct weapons of war, much like those who worked on advancements in airplanes and submarines during World War I and World War II. After the Wright brothers successfully flew an airplane in 1903, interest in rocketry increased. Mathematicians focused on calculating velocity and trajectory, while many other researchers began studying propulsion systems.

Robert Goddard, an American scientist, successfully launched the world's first liquid-fueled rocket in March 1926. In 1919, Goddard published *A Method of Reaching Extreme Altitudes*, a report that explained his theories of rocket-propelled flight. In the report, Goddard mentioned the possibility of reaching the moon with a rocket. This theory caused an uproar among the scientific community and the public. While many people ridiculed the notion of moon travel, others found the idea exciting and plausible. Though controversial at its publication, the report is now viewed as one of the germinal works of rocketry science.

Goddard's first rocket traveled only meters in height, but he and his team continued to work on the technology. By 1941, Goddard had launched 34 rockets, the most successful of which traveled 1.6 miles. Goddard's 214 patents make him one of the great rocketry scientists and the father of modern rocketry and the space age. Nonetheless, the U.S. government was unenthusiastic about funding rocketry research. This left the next generation of rocketry advances in the hands of European scientists.

Germany would conduct an immense amount of research into the deployment of rocket missiles to ensure that they would not violate a treaty after World War I. Long-range artillery was the key solution for new weapons; the A2 rocket was created, and its successors were developed into the very first missiles, which would be

used in World War II. With further research and development, the V-2 was the world's first military ballistic missile and was the prime foundation for many rockets that borrowed its design around the world. During the last months of World War II, many German scientists were captured by or surrendered to the United States and the Soviet Union, bringing along their extensive knowledge of rocketry. The arms race would be fierce, as now both of these world powers gained rocketry knowledge that used to be in the hands of German scientists and engineers. The achievements led to many of the world's first space experiments. October 4, 1957, is regarded as the first day of the Space Age. It was the day that Sputnik, a Russian satellite, was first launched, and the world catapulted into a fascination with space travel.

The United States made a significant commitment to fund rocket-powered space flight. In 1961, President John F. Kennedy announced that NASA would land a manned rocket on the moon by the end of the decade. The birth of the Apollo program allowed for huge strides in rocketry science that culminated in the 1969 moon landing. NASA's reusable, low-earth orbital program, known as the Space Shuttle program, combined rocketry with aircraft technology. Shuttles used solid rocket boosters to make 135 missions between 1981 and 2011.

In the late 20th century, hobbyists took up rocketry as model rockets became commercially available. Water, hydrogen peroxide, and other materials fuel hobby rockets, which come in three categories: low power, mid power, and high power.

Rosie the Riveter

The “Rosie the Riveter” icon began as a propaganda symbol that encouraged a collective effort from all American women during World War II (1939–1945). In another sense, Rosie was a symbol of the wartime sacrifices and discrimination that women endured during the war. In later years, feminists redefined the Rosie the Riveter image as a symbol of female empowerment. Though this iconic poster is but one of many images that encouraged women in World War II to take on war work, it is the most famous. The “Rosie the Riveter” campaign encouraged American women to think of their waged labor as positive and patriotic. During the war, there was a shortage of labor in the factories, because millions of men had gone off to fight. To keep the country running and to provide the troops with needed materials, the federal War Manpower Commission and the Office of War Information (OWI) began a large propaganda effort known as the “Women in War Jobs” campaign. The campaign first targeted women already in the workforce by encouraging them to seek higher-paying wages in factories. Then, the campaign recruited young girls out of high school. Finally, when officials realized that even more workers were needed, they targeted older married women who had children and had not previously been expected to work outside the home.

Many ads appealed to patriotism. One ad advised, “Do your part, free a man for service.” Other ads told women that if they joined the workforce, the war would be over sooner. Some ads attempted to generate fear and guilt by telling women that more soldiers would die without their help. Furthermore, many propaganda posters underscored the specific dire need for industrial workers, and industrial leaders advertised high wages. Not surprisingly, about half of all women in the workforce during the war were employed in defense-related industries. About 6 million women answered the call. Some worked under very dangerous conditions in munitions factories. Many did heavy factory work that had been previously reserved for men: building aircraft and warships. Women drove streetcars, operated heavy construction machinery, and unloaded freight. Women were toolmakers, machinists, lumberjacks, blacksmiths,

steel mill workers, railroad workers, and riveters who built war machines.

Artists celebrated Rosie the Riveter in popular songs and paintings. Norman Rockwell painted a female riveter for the cover of the Memorial Day edition of the *Saturday Evening Post*, using a dental hygienist named Mary Doyle Keefe for his model. Rockwell's figure's pose resembled the pose of the prophet Isaiah in Michelangelo's Sistine Chapel ceiling painting. In a patriotic vein, an American flag waved behind a redheaded Rosie wearing a blue uniform with white pins on her chest. Evidence of the riveter's work ethic could be seen in the residue on her face and arms. As if to show that women's industrial work could help defeat Adolf Hitler, a riveting gun lay on the worker's lap while a copy of *Mein Kampf* lay under one of her feet.

After Rockwell's portrait was published, the press found and celebrated several real women they could associate with the powerful image, the most famous of these being Rose Will Monroe, who worked as a riveter on B-24 and B-29 bomber airplanes in Ypsilanti, Michigan.

After the war, the image of Rosie the Riveter was almost forgotten. It was not until a wave of feminism swept the nation in the 1980s that the concept of Rosie the Riveter was resurrected. However, due to copyright restrictions on Rockwell's work, feminists adopted a woman's image from an earlier painting. In 1942, the Westinghouse Power Company had commissioned J. Howard Miller to design a propaganda poster to use to increase the morale of its workers. Miller created a poster of a woman wearing a bandanna and flexing her arm muscle with a caption reading, "We Can Do It." Since the 1980s, the Miller poster has become one of the most recognized symbols of female empowerment. In this way, the Rosie the Riveter image went from being used as a wartime recruitment propaganda tool to a symbol of past injustices and a rallying call for women's empowerment.

Women who took jobs in industrial work often faced negative attitudes from male coworkers. In extreme cases, factory managers refused to provide women with gender-separate restrooms. Although women usually earned more doing factory work than

any other work, they were sometimes paid 50 percent less than their male factory coworkers. In addition, women were often denied access to certain hazardous but higher-paying occupations, such as sandblasting. Promotions in pay and rank were often given only to men. African American women, usually employed as factory janitors and sweepers, remained even lower on the job ladder than white women.

After the war, both commercial and military sectors wanted women to leave the factories so that returning men could have their jobs. Consequently, the government launched a new propaganda campaign asking women to "return to normalcy." The message was that it was not "normal" for women to work in factories. The crisis of war was over, and the aid that women had provided was no longer needed. In short, Rosie the Riveter was laid off in 1945.

Working in the factories had demonstrated to women and to the world that they could do jobs that had been previously thought exclusively suited to men. In fact, although many women were let go from their factory jobs in 1945, an increase in postwar spending brought many women back to the factories a few years later. Even by 1947, the percentage of women in the workforce had risen to the same level it had been in 1940. In the long run, women's work experiences during the war served as a precursor to the more permanent employment opportunities that women enjoyed in the 1970s and 1980s. Today, Rosie the Riveter is a symbol of not only what was but also of what can be.

Primary Document: Excerpt from Interview with Maria Isabel Solis (2003)

Americans scrambled to fill all the wartime jobs created by the United States' entry into World War II. Women of all types and classes worked in wartime factories, doing the kind of heavy industrial manufacturing previously thought only the province of men. Maria Isabel Solis Thomas worked in a shipyard with women from all over the country. Her experience was both empowering and life changing, in part because she learned that she and other women could do what people said they could not do.

Maria Isabel Solis Thomas: When we went to work in California, my sister and I, we, oh my god . . . there were girls there, oh my god, from all over . . . They were Italians or they were Portuguese or whatever, but then there were a lot of Mexican girls, real nice girls. They, like I say, they were from Denver, Colorado, they came from Seattle, Washington, they were, well, they was far from Pennsylvania, there was some girls that came from over there 'cause their families had moved there and I went to work in a shipyard we met all these girls from all over and we were staying in these, ah, we ourselves in these girls dormitories. When we went over there, realize real neat, everything was so beautiful we thought oh, it looked like when you're in school, in girls' dormitories, you go someplace else you know all the girls and it was so beautiful, everybody friendly and conversing with one another and all of that, but I'll assure you one thing that I would say that about at least 40% of the people that were there they were Mexicans—Mexican girls. We got up at three o'clock in the morning, got ready by five, took off at five, 'cause we have to be at work by six but we stop on our way at a little restaurant and had breakfast, and took our lunch, and whatever, and went to work.

Interviewer: So what kinds of things were you doing at work?

2

Maria Isabel Solis Thomas: Oh well we had to . . . it was dangerous . . . and it was dangerous and, ah, we, ah wherever there was needed . . . see . . . it concerns us . . . was pipes . . . nothing else . . . plate was somebody else who had to weld the plates and

different things. We, it was the pipes, the pipes on the railings, pipes that were the water pipes, this pipe, whatever pipe, and the most, how can I say, delicate and stuff it was a tiny, tiny little pipe that came in the front of the ship and it was a little stand like this, a platform on the top you know with the holes on it or whatever . . . it stood on a base no higher than . . . and oh my god. And then they wanted me to get under there, in the center, there was a little pipe coming out, that, well, was the radar. And it's very delicate. And you have to know precise, exactly precise how to strike the rod and at the same time how to weld around, clear around it and seal it, see, 'cause it had to be sealed. And not to make a hole, not to do damage to it.

And oh my goodness . . . and we were really, we were very thin, we were very small, just kids, like I say kids, but we were very thin. We were always playing . . . making exercise and what . . . I think that's why, and we walked a lot, and so we were very thin, short and thin, but then we have to wear all this uniform—this stuff—we wore coveralls, and then we worked, on top we wore. I wish we could have been able to take pictures of ourselves over there . . . we were not allowed—not in the shipyard or any place around there—nobody could take pictures. There was a war going on, you ain't gonna be taking pictures of no shipyards or anything but anyway . . .

Interviewer: But World War II had already started?

Maria Isabel Solis Thomas: It was under full force. There was in [19]44 there was in full force, and that's why they needed us to go and help 'em build these ships, to get 'em out, 'cause they needed the ammunition, they needed the food, and [to] transport these boys where they had to go, okay?

And so, like I say at that time, to crawl under there, and with all of this mess that you had, so I had to take just about everything, all these things off, and just a hood, in my glasses they give you, so that you won't burn your eyes and get under there, crawl under there, and seal it. I was so proud, 'cause man, I did it just exactly the way they wanted to, and here I come up and [they say] "Hi Shorty, you did pretty good!" [Laughs] But anyway, at the same time, it was fun for

us you know, crazy kids, but at the same time we were very proud that we were doing something good, something to help, to help the boys really, we never thought about being patriotic or being . . . because we were doing it for our country though we believed that we were helping these boys, these young men that were out there and were going out over there. 'Cause and we see 'em when they were shipped out and oh, their sad faces and everything, it was very hard. And so I don't know, it's . . . I can't explain, but it's very hard. It's very hard. And so if we're going over ____ [?] ____ , I was wearing little bitty earrings that had a tiny little bitty cross, and he looked right at me so funny, and he says "Can you give me one of your earrings?" I looked at my earrings and said, "Oh boy," and my sister looked at me and I look at—we're standing there like fools you know—but I had the turban, and at the same time I guess it come out and you could see it I was always wearing earrings, my goodness, for my sister always used to say "She's got no shoes on, but she's gotta wear earrings." So anyway, and so I felt sorry for him, and I took it off and gave it to him, and then the other boy, it was the other sailor that was there, you see they were crossing they were going into their ship, he says "How 'bout the other one?" I said OK so I took it out and I gave it to the other boy. We never seen them again, I don't know who they were or whatever, but anyway it was sad . . . it was sad. Anything, any little thing, it means something to them.

Maybe to remember the girls who were there or whatever, but uh . . .

Interviewer: Did you have a lot of contact with the soldiers?

Maria Isabel Solis Thomas: No. No, no, no, no this is when they were boarding their ship. See, they brought in their ships when they were damaged . . . in there and we got to see 'em. It was very sad. But then . . . but then . . . no, no, our job was to do the work, to do the work there wherever we were needed, whether at the top of the deck, whether it was to the bottom or on to the boiler room, everywhere we were needed we went. This was, it was dangerous, it was because there were some places that were very, very dangerous, even for a man, and yet we kids went and did the job without even, without a second thought. That's what they needed, we were gonna do it. And thanks be to God everything was fine. We were both fine, and in fact and like I say on some of these . . . that's when we had the rest, then we would go and visit or go into San Francisco, we just a few miles from there. Pick up the bus and go with a whole bunch of girls . . . Lina, Rosa, Virginia, this that girls from all over the country, I tell you it was like this . . . all women!

Schwinger, Julian (1918–1994)

Schwinger was a revolutionary American scientist known for his contributions to the quantum theory of electrodynamics. His work won him a Nobel Prize in Physics in 1965. Schwinger became an early scholar in physics, publishing his first work at age 16. He received his PhD in 1939 from Columbia University. Schwinger quickly moved on to work at the University of California, Berkeley.

In his first year at Berkeley, Schwinger became a National Research Fellow in physics, and the following year he became an assistant to Julius Robert

Oppenheimer, the well accepted "father" of the atomic bomb. In 1941, Schwinger became an instructor at Purdue University, and by 1942, he had become an assistant professor.

Life took a more serious turn for Schwinger in 1943, when he was enlisted for the technological battle in World War II. Schwinger originally had been given leave from Purdue to assist at the Radiation Laboratory at the Massachusetts Institute of Technology. This led to Schwinger being asked to help with the development of the atom bomb in Chicago. Schwinger's distaste for the bomb caused him to move to Boston, where he worked with a former teacher of his,

Dr. George Eugene Uhlenbeck, on radar. Schwinger was a dedicated night worker and was cited by Uhlenbeck as being mathematically adept. During his time of leave at Purdue, Schwinger was granted the title of research professor in theoretical physics. Despite this, when Schwinger's assistance with war efforts ended as the war did, he opted to resign from Purdue in favor of a position at Harvard, where he would work for 27 years (1945–1972). He began as an associate professor in 1945 but quickly was promoted to a full professor in 1947. Also that year, Schwinger married Clarice Carroll.

At this point in his life, Schwinger began to turn to theoretical work more than practical. In 1951, he coined the phrase “Schwinger effect,” an idea in thermodynamics that has not been confirmed by an experiment yet; he also was granted the first Einstein Prize that year.

Schwinger's big breakthrough came in 1957, when his work led him to the discovery and invention of source theory, which is largely responsible for the basic scientific understanding of nearly everything physical. This work is predominantly why he became the joint winner of the Nobel Prize in 1965 with Richard Phillips Feynman, who had researched the findings that Schwinger discovered. Schwinger's discovery is notable for putting quantum mechanics in alignment with Einstein's theory of relativity.

Schwinger's life transitioned to focus more on the development of new scientists in his later years. Schwinger moved from teaching at Harvard to the University of California, Los Angeles, in 1972, where he stayed until his death in 1994. Schwinger's nearly 60 years of contributions to physics in the 20th century, as well as his capability as a teacher, have made him one of the most impactful characters on science in the modern era.

Semple, Ellen Churchill (1863–1932)

Ellen Churchill Semple was an American geographer, author, and educator. She was one of the first female professional geographers in the United States and was the first woman to serve as president of the Association of American Geographers. Her theory of environmental determinism, although controversial by the mid-20th century, shaped the field of human geography.

Semple was born on January 8, 1863, in Louisville, Kentucky, to Alexander Bonner Semple, a successful businessman, and Emerine Price. The youngest of five children, all daughters, she followed her older sister, Patty, to Vassar, graduating with a BA in 1882. Upon her return to Louisville, she turned her scientific interests to her Kentucky surroundings, studying local populations and constructing her theoretical framework of environmental determinism—the idea that the natural environment controls a population's history and culture. In 1891, she earned an MA from Vassar for her thesis, “Slavery: A Study in Sociology.”

While visiting London in 1887, Semple met Duren John Henderson Ward, who introduced her to the work of his professor, Friedrich Ratzel. Ratzel founded a discipline called anthropogeography, now referred to as “human geography,” at the University of Leipzig. Semple studied with Ratzel between 1891 and 1893. Although women could not matriculate at Leipzig, Semple obtained permission to attend Ratzel's lectures, as well as seminars in economics and geography. With his encouragement, she began publishing her geography writing. In 1901, she published *The Anglo-Saxons of the Kentucky Mountains*, a detailed, fieldwork-based study of the eastern part of the state and its people before it was altered by coal mining.

In 1903, she published *American History and Its Geographic Conditions*, which brought her national

attention. She became a charter member of the Association of American Geographers in 1904, one of only two women invited to do so. In 1906, she was appointed lecturer in geography at the University of Chicago, and as an educator, she emphasized the importance of fieldwork and original research. Her next book, *Influences of Geographic Environment*, appeared in 1911 and introduced Ratzel's theories of anthropogeography to American audiences. She attempted to demonstrate how various elements of the natural environment affected human culture, social development, and migration.

In 1921, Semple was elected president of the American Association of Geographers and received her first full-time academic appointment as a professor of anthropogeography at Clark University. She was the first female faculty member at Clark, though the university paid her significantly less per year than male faculty members, arguing that she was a woman without dependents. Her final book, *The Geography of the Mediterranean Region: Its Relation to Ancient History*, was published in 1931. It described how the landscape of the Mediterranean basin gave birth to Western civilization. By this time, however, the theory of environmental determinism had fallen out of favor with mainstream geographers, and the book was largely ignored. Semple died on May 8, 1932, in West Palm Beach, Florida.

SONAR

Sonar, also known as SONAR, an acronym for “sound navigation and ranging,” a term first coined by the U.S. Navy during World War II, is a method of harnessing sound energy to communicate and sense objects primarily through the medium of water. Sound

Increased interest in detecting submarines during World War I led to the development of sonar. Sonar machines, like the PC-488, could send out sound pulses and measure their return when reflected off a hard surface. (Corbis via Getty Images)

waves have a distinct advantage in transmitting information underwater due to their higher range of penetration as compared to electromagnetic waves. It is for this reason that sonar eventually became instrumental for antisubmarine warfare in naval forces.

Sonar systems generally fall into one of two groups: passive systems or active systems. In passive systems, objects to be detected are the primary source of signal generation; signals are detected by the observer through a receiver. On the other hand, active systems, also known as echo-ranging systems, generate a signal through a transmitter, which then radiates toward an object and is reradiated back to the receiver.

Although previous efforts to exploit the propagation of sound waves underwater have been recorded as far back as 1490 by Leonardo da Vinci, it was not until 1906 that American shipbuilder Lewis Nixon, inspired by the need to detect submerged icebergs at sea,

created the first sonar device. However, in 1912, the RMS *Titanic* struck an iceberg in the North Atlantic Ocean, which caused it to sink. This incident was one of two significant events that acted as a catalyst for increased attention to the development of sonar technology. Soon after, in 1913, a patent was awarded to Canadian American Reginald A. Fessenden for his underwater transducer, which was capable of detecting an iceberg 3.2 kilometers away.

As sonar continued to evolve, so did political tensions throughout Europe. By 1914, the world had entered the First World War. Submarines became a premier threat in naval warfare because of their ability to go undetected by traditional observational systems. Both the British and U.S. militaries aggressively sought to exploit echo-ranging technology as a solution to this new military dynamic. By 1919, ships equipped with Allied Submarine Detection Investigation Committee (ASDIC) systems were capable of detecting objects while in motion.

Over the next several years, the U.S. Navy reduced its sonar frequency from 20–50 kHz to 15–20 kHz, thus increasing its range. During the Second World War, sonar had become a powerful tool for locating enemy ships, and nearly all U.S. destroyers had echo-ranging technology. This proved to be effective and played a paramount role in controlling ocean territory.

Apart from military operations, sonar has been used in many other applications including fisheries, ocean floor mapping, unmanned underwater vehicles, and submerged airplane retrieval systems. Echolocation, the biological equivalent of active sonar technology, is used as a form of communication by animals such as bats, dolphins, and even some humans who suffer from blindness.

Submarine Technology

A submarine is a type of watercraft that can operate underwater. Submarines were developed in the early 18th century and have considerably changed over the years. The key importance of the submarine was its strategic advantage for military use. Submarines were key in performing naval tasks such as protecting aircraft carriers, reconnaissance missions, and other tasks.

Submarine technology advanced significantly during World War II and the late 20th century. Pre–World War II submarines peaked in prominence through advances made by German engineering. Called U-boats, German submarines were known for their ability to withstand high water pressure as well as to adjust for buoyancy when diving below the water’s surface. Its structure was that of a cylindrical boat with two hulls: an inner hull and outer hull. The purpose of the inner hull, also called the “pressure hull,” was to protect the crew working inside from the intense water pressure and freezing temperatures of the deep sea. The outer hull took the shape of a cylinder. The U-boat had tanks throughout that controlled its buoyancy. It also included internal combustion engines and a periscope. These 200-ton U-boats were also equipped with torpedoes, deck guns, and mines. The German U-boat was the most formidable naval weapon of World War I.

Submarine technology continued to accelerate during World War II. The Allies and Axis each had about 2,000 vessels serving in the war. German U-boats were known in World War II for their ability to block the supply routes of the Allies, though both sides wreaked havoc on the other during the war. Winston Churchill commented once that German submarines had had such a significant damaging effect that they almost led to British surrender. The Vetchin-class U-boat had an improved engine and greater fuel capacity. These submarines were about 500 tons

and had diesel-electric engines. They were armed with six torpedoes and 20 mines each, and had other improvements.

During World War II, most U.S. naval submarines were 300-foot, 1,450-ton crafts armed with dual-purpose guns, automatic weapons, and torpedoes. Navigation advances in the periscope provided the observer in the submarine with a view of the surface of the sea. In this war, there were improved torpedoes as well as improvements to radar. Early radar models gave insight to when an aircraft appeared nearby, but during World War II, radar could sweep the surrounding sea for targets. Its plan position indicator displayed an image on a screen, providing a clear indication of targets' positions. Improvements in submarine technology allowed the United States to sink about 5 million tons of Japanese merchant shipping during the war. Submarines also sank over 550 Japanese ships.

Toward the end of World War II, snorkels were added to submarines. The snorkel allowed fresh air into the vessel for breathing and to ventilate engine exhaust fumes. This enabled the submarine to stay below surface with its engine running while recharging its batteries.

After World War II, in 1954, the United States issued the world's first nuclear-powered submarine, the USS *Nautilus*. Nuclear submarines were quiet and heavily armed. They could stay underwater until their food supplies were exhausted. The *Nautilus* outperformed all other submarines at the time because of its overwhelming effectiveness and power, in great part because it ran on controlled nuclear fission that converted water into steam for its turbines. The engine had two systems of pressurized water sent throughout the engine. One system circulated water throughout the reactor and eventually reached the steam generators. The water reached the secondary system of water, where it was heated into steam. The steam entered the turbines to generate power for the submarine and was then condensed in tubing, reverting it into water. This system allowed the submarine to be submerged for long periods and to move at immense speed. In 1958, the *Nautilus* crossed beneath the Arctic ice cap and was also able to circumnavigate the world in 1960.

Nuclear weapons were implemented into the submarines, as well as changes to their shape. Structural

changes gave them a teardrop shape, allowing vessels to dive into the water at a top speed of about 40 to 45 miles per hour. During the Cold War, the U.S. Navy continued to develop different types of nuclear-powered submarines. The first type was the strategic deterrence patrols (SSBNs) equipped with nuclear missiles. The continually moving position of the SSBNs made them difficult to track.

Hunting submarines were equipped as seek-and-destroy enemy patrols. Special operations submarines were deployed on special occasions to fulfill particular national agendas. Each of these nuclear submarines was equipped with different missiles. A Tomahawk cruise missile could strike at faraway target with accuracy, while the Polaris ballistic nuclear-armed missile launched from a concealed location but with low accuracy. The Poseidon missile later replaced the Polaris; it was more accurate and had greater range.

Advancements in submarine technology continue. In the 21st century, although major submarine combat has dropped significantly, submarines still have the ability and power to drastically affect the future in many ways.

Tampon

A tampon is composed of material, usually cotton, that absorbs menstrual fluid when placed inside the vagina.

The idea of tampons is not new. Ancient Egyptians made tampons from softened papyrus, while

ancient Greeks used lint. The modern menstrual tampon, which consists of a plug, applicator, and string, was invented in 1929 by American osteopathic physician Earle C. Haas (1888–1981). In 1931, Haas applied for a patent for his invention, and in 1933, he sold his patent and trademarked brand name “Tampax” (which he created by combining the words “tampon” and “vaginal pack”) to Gertrude Tenderich for \$32,000. Tenderich, an immigrant from Germany, started the Tampax Company in 1936. She made the first Tampax tampons using her own sewing machine.

Although the tampon has since had a major impact on how women treat their menstrual flows, the public initially resisted menstrual tampons. Women also questioned the hygiene of the tampon and worried about its impact on female virginity. Many were afraid that the device might lead to irritation, menstrual blockage, infection, and even sterility. In the 1940s, advertisements in the *Journal of the American Medical Association*, national newspapers, and popular ladies’ magazines used patriotism to attract would-be users by proclaiming that tampons freed up raw materials that could be used in the World War II effort. Tampax reinforced these cultural messages by sending “demonstrators” to local department stores to sell their product in person. By the end of the decade, one out of every four American women used tampons.

In the post–World War II years, as American women became more active in the workplace and in organized athletics, tampons gained increasing market acceptance. By highlighting the idea that tampons were more discreet than pads (they are less bulky and do not show under clothing), advertisers convinced a whole generation of women to replace their “old-fashioned” sanitary napkins. Today, tampons are most popular among American women; around 70 percent of menstruating women in the United States use them. According to Karen Houppert, as of 1999, only 3 percent of Asian and Latin American women used tampons, which may be linked to the importance placed on physical (that is, hymeneal) virginity in these regions of the world.

In the late 1970s and early 1980s, researchers found that some tampons caused toxic shock syndrome (TSS). Though incidents of TSS were rare, the public reaction against tampons in general was

considerable. In the 20th century, tampons have come to represent unhealthy and environmentally unfriendly products for many women. Critics suggest that bleached, mass-produced cotton exposes a woman’s body to carcinogens and other potentially deadly substances. Moreover, cotton is an environmentally unsustainable agricultural product requiring massive amounts of water, pesticides, and chemical fertilizers. Tampon alternatives include more environmentally friendly products such as organic sanitary pads and reusable or disposable menstrual cups (the most popular brands are the Keeper, Moon Cup, and Diva Cup), which resemble diaphragms but are intended to trap menstrual fluid.

Tea Bag

Tea bags, defined as small, porous bags filled with tea leaves or powder and immersed in hot water to make individual portions of tea, are a relatively modern invention. For thousands of years, the brewing of tea required precise measurement and steeping times, in addition to careful removal of the leaves before consuming the beverage. The invention of the tea bag streamlined the process and reduced waste by allowing individuals to brew tea by the cup. Thomas Sullivan, a tea merchant from New York, is generally credited for accidentally inventing the tea bag in 1908. However, the modern tea bag was actually invented at least seven years earlier; Roberta Lawson and Mary Molaren filed a patent for a “tea leaf holder” in 1901.

The practice of boiling plant leaves to make a tea originated in China between 3000 and 1600 BC. Tea

was prepared by steeping loose tea leaves in hot water for an optimal length of time and then straining the brew before consuming it. The tea infuser became popular in the mid-1800s. These encase the leaves in a wire mesh or perforated metal ball and can be removed from the water at the right time.

The first patent for a tea bag was issued to Roberta C. Lawson and Mary Molaren of Milwaukee, Wisconsin—their “Tea Leaf Holder”—on August 26, 1901. According to their application, the practice of spooning loose tea leaves into a pot “involves the use of a considerable quantity of tea leaves to prepare the desired supply of tea, and the tea, if not used directly, soon becomes stale and wanting in freshness, and therefore unsatisfactory, and frequently a large portion of the tea thus prepared and not used directly has to be thrown away, thus involving much waste and corresponding expense.”

Lawson and Molaren’s solution was very similar to modern tea bags. The tea leaf holder was made of a sleeve of loosely woven cotton fabric folded over on itself, with the flap fastened on top. The single-serving packet of tea was placed in a cup and hot water poured over it to produce “only a cup of tea fresh for immediate use.” They were granted U.S. Patent 723,287 on March 24, 1903, but they were unable to market their invention on a large scale.

In 1908, merchant Thomas Sullivan decided to save money by packaging tea samples in small silk bags instead of metal containers. The bags were intended to be emptied before brewing the tea, but his customers found it easier to infuse the tea directly with the bag and then discard the bag of spent tea. Sullivan later began using more porous gauze fabric.

Innovations over the next century made it more convenient to brew an inexpensive cup of tea. In 1930, the Salada Tea Company purchased William Hermanson’s patent for a heat-sealed paper tea bag, which eliminated the need for stitching or gluing the bags. In 1952, the Lipton Tea Company patented its “Flo-Thru” tea bag with a double-chambered bag that decreased brewing time by increasing the surface area between the tea and water.

Today, tea bags are used in 65 percent of American households. In spite of their efficiency, tea drinkers debate about the advantages of using tea bags over

loose tea. Of concern is that tea bags contained crushed tea leaves rather than whole-leaf tea and that the bags are not large enough for whole-leaf tea to expand properly. Premium tea companies have improved flavor by packaging tea in silk fabric bags, which may be hand sewn as well. Fillings include whole-leaf tea enhanced with herbs, spices, and dried fruits.

Telephone

Although Alexander Graham Bell (1847–1922) was credited as the inventor of the telephone, a device that sends and receives sound such as voice messages and data across great distances, it was the product of the work of many scientists and inventors. Early attempts to create a viable telephone were based on existing telegraph technology and a desire to improve it.

Bell was the first to secure a patent for the telephone. However, Bell suffered many legal challenges to the legitimacy of his claim. But he successfully defended his patent, and, with the help of several financial backers, the company he formed became one of the largest corporations in world. The telephone industry produced many innovations that enhanced the telephone as well as other areas of endeavor. In short, telephone technology transformed the world in so many ways that life without it soon seemed inconceivable.

Like his father, Bell was a teacher of the deaf. He had a strong enough foundation of acoustics and

speech to secure employment as a teacher at Boston University in 1873, two years after emigrating from Scotland. But he was not trained as a mechanical scientist or an inventor. He knew little about mathematics, physics, or engineering. The telephone was the first device he attempted to invent. In fact, his interest in inventing began in 1872 when he attended a lecture at the Massachusetts Institute of Technology (MIT) on experimental mechanics delivered by Professor Charles R. Cross. After the lecture, Bell struck up a friendship with Cross, and for several years, the two men collaborated.

Bell made friends with two influential residents: Thomas Sanders (a wealthy merchant) and Gardiner Green Hubbard (a businessman and politician). Bell convinced Sanders and Hubbard to fund his research. They provided him a workshop, and they paid the salary of a skilled assistant named Thomas Augustus Watson (1854–1934). According to patent requirements at that time, applicants did not have to produce a working model. Instead, Patent Office officials based their acceptance or rejection of applications based on known technical knowledge. After his patent was granted in 1876, it took Bell an additional three years to improve his prototype to the level he had proposed in his application.

The two major discoveries required for the invention of the telephone were electromagnetism and induction. Scientists had known about these forces for about half a century before Bell secured a patent. In 1820, Hans Oersted (1777–1851), a Danish scientist, discovered the properties of electromagnetism, and in 1831, Michael Faraday (1791–1867), a British scientist, discovered induction.

The first recorded use of these forces to transmit and receive sound happened by chance. Antonio Meucci (1808–1889), an Italian caregiver, built a machine that used electric shocks to allegedly treat various illnesses. In 1849, while treating a man with migraines, Meucci placed a copper electrode in the patient's mouth and another in his own mouth to gauge the strength of the current. When the patient yelled, Meucci felt the sound via the electric vibration of his own electrode. Meucci filed a caveat at the U.S. Patent Office for his discovery of "Physiophony" (sound projected from a human body

through wires). The caveat gave him patent priority for one year. However, he failed to develop a practical prototype, and his caveat lapsed.

By the 1850s, long-distance communication could only be achieved through the use of the newly invented telegraph. There had never been anything like it. For the first time in human history, people were able to communicate over long distances within a matter of minutes. Unfortunately, the technology had some notable drawbacks. For example, to send a message, a trained specialist had to code and tap the message out in Morse code (a system of dots and dashes). In like manner, for the message to be successfully received, another trained specialist was required to listen to and decipher the code. Building on electric telegraph technology in 1854, Frenchman Charles Bourseul (1829–1912) published a seminal article in *L'Illustration*, a French journal, where he theorized about the possibility of transmitting intelligible spoken words with the use of electric wires. If this were possible, the long-distance communication system would become a lot less cumbersome.

In 1860, Philipp Reis (1834–1874), a German science teacher, built a device intended to transmit sound with the use of electricity. Reis's "Telephon" was said to use the power of sound waves to vibrate a parchment that produced loose contact between two platinum plates. The vibrations produced an electric signal that then traveled through a wire to a resonating receiver box. Witnesses claimed that they heard Reis's device successfully transmit and receive speech and music. In fact, for the next quarter of a century, many Germans believed that Reis had invented the telephone.

In 1874 (the year Reis died), Elisha Gray (1835–1901), an American electrical engineer, started working on a "harmonic telegraph," which he hoped would transmit several telegraph messages simultaneously at different pitches. During his experiments, Gray became convinced that his device had the potential of also transmitting spoken words, and on February 14, 1876, he applied for a caveat. Bell applied for a patent for his own "harmonic multiple telegraph" on the same day. Bell was awarded the patent (good for 17 years), but there was some controversy over who had applied first that day. The long history of the development of

telephone technology and the patent controversy led to more than 600 lawsuits over the next two decades. Bell won all of the cases.

In one of the highest-profile cases, the Reis family sued Bell for stealing the rights to telephone technology. The court found in favor of Bell's patent for two main reasons. First, Reis's notes revealed that he did not understand the workings of his own invention. His notes stated that his transmitter operated by "making and breaking" electrical contact when, in fact, the device contained a loose-contact microphone that was set up to send an undulating current. Second, and most important, the Reis camp was unable to get the device to work during the trial. In contrast, Bell was well versed in the workings of his own device, and he was able to demonstrate it at will. Ironically, in 1946, 24 years after Bell's death, an examination of Reis's prototype by an expert from Standard Telephones and Cables (STC) showed that it suffered from low amplification but that it was capable of producing intelligible speech when connected to a modern receiver.

The most serious challenge to Bell's patent was launched by Western Union (WU), which employed Thomas Edison and Elisha Gray to develop a competing telephone and telephone system. WU operated on the notion that Gray—not Bell—was the true inventor of the telephone. WU developed the first telephone switchboard and the first telephone directory. Seeking to stamp out his most aggressive competitor, Bell sued WU for patent violation and won.

With financial backing from Sanders, Hubbard, and others, Bell launched the Bell Telephone Company (BTC) in 1876. The first commercial telephone that BTC introduced a couple of years later was housed in a wooden box. It had a mouthpiece that doubled as an earpiece and a thumper to signal incoming calls. Without competition, the National Bell Telephone Company (NBTC), founded in 1879, grew rapidly. NBTC began by providing telephone services at high rates to businesses in large cities and later to residential customers. By 1880, NBTC had more than 60,000 customers in the United States alone.

In England, Edison took the lead with the telephone industry. However, within a few years, Bell and Edison's interests in England merged. Mostly due to the constant lawsuits that had taken a toll on him, Bell

retired from the telephone industry a very wealthy man in 1881. During his retirement years, he spent his time designing and building flying machines. When Bell died in 1922, AT&T paid tribute to him by disabling telephone ringers across the nation for one minute.

Void of an existing infrastructure, the primitive nature of telephone technology required many telephone line connections. Within a couple of years, the street-level skylines of large cities like New York were considered ruined by unsightly, spider web-like telephone wire formations. The first solution was to install lines underground. While crews were busy digging up city streets, NBTC came up with a second and more economical solution. NBTC borrowed WU's switchboard idea, which dramatically reduced the number of required lines.

NBTC's use of switchboards created employment opportunities for thousands of women. In 1885, NBTC also established the American Telephone and Telegraph Company (AT&T) to provide the first nationwide long-distance network. NBTC went through several transformations and name changes until it was absorbed by AT&T in 1899. For many reform-minded journalists, by the late 1800s, the AT&T corporation had come to represent greed, poor quality, and terrible customer service. However, in the early 1900s, financier J. P. Morgan (1837–1913) transformed the company into a model for modern corporations.

To keep costs down and maximize profits, in 1914, AT&T formed alliances with a variety of companies from around the world that produced low-cost telephone equipment. To foster innovation in telephone technology and stay ahead of other competing telephone companies in the 1940s, AT&T created Bell Labs. In 1948, Bell Labs created the transistor, which replaced the vacuum tube in telephone networks. Compared to vacuum tubes, transistors were less expensive and much smaller. In 1956, Bell Labs was awarded the Nobel Prize for the introduction of the transistor, which had applications far beyond telephone use. Bell Labs developed cellular phone wireless technology (1947), the computer modem (1957), and communication satellites (1962) that orbited the earth and facilitated worldwide telephone communications.

In 1965, the development of electronic switching systems permitted a vast increase in telephone traffic

and also set the stage for later Internet traffic. By the 1980s, AT&T employed more than 1 million people. The federal courts ruled that AT&T was a monopoly and ordered that it be dismantled. In 1984, when it was broken up, the company's assets totaled about \$155 billion, which was more than the assets of General Motors, Mobil, and Exxon combined.

The telephone transformed society. It changed the way that business was conducted. For example, customers could save on travel expenses and time by calling stores to find out if certain items were in stock or by quickly making price comparisons. In like manner, the telephone changed the way that medicine was practiced. The telephone could instantly link patients, doctors, and pharmacies. Certainly, the speed with which emergency and rescue crews could provide services was greatly enhanced by the advent of telephones. Telephones changed the way that businesses were run. Since the telephone allowed salespeople to report to their bosses and get orders from them from long distances, they were able to function on a regional and national level.

The social influence of telephones was also extremely profound. The telephone allowed families and acquaintances who were separated by great distances to speak to each other. It also allowed them to communicate more often than ever before. In a powerful way, the telephone dissolved distance. For example, it connected rural and farm areas with cities and urban centers. It allowed people from different nations to speak to each other at the speed of light. Cellular phones, which connected wirelessly to the Internet, allowed users to access a variety of information, including sports scores, soap opera updates, and up-to-date bank balances. It did not take long for people to become accustomed to the luxury of telephone technology. In fact, most people soon found it difficult to conceive of life without a telephone—a condition exasperated by the invention of the mobile or cell phone.

Television

Television technology, a system for transmitting and receiving both visual images and sound, was developed and improved by many people. Television technology operates on two major principles. First, the human brain has the ability to reassemble dots (pixels) into images. Second, the human brain can view a series of successive pictures and from them, form a single flowing image. Both early rival television designs capitalized on these two human traits.

Although the popularity of electronic television technology began slowly, after prevailing over mechanical television technology, electronic television quickly became a fixture in American life after 1945. In fact, it has made an indelible mark on American daily life, culture, and politics. Improvements in picture quality (including color and high definition) and functionality (including compatibility with peripherals) served to foster America's fascination with television.

Paul Nipkow (1860–1940), a German engineer, was the first to patent a type of early television technology in 1884. Nipkow's mechanical design employed a disk with holes that spiraled through it. When light was projected through the spinning disk, it produced images on a photosensitive cell. In truth, Nipkow never constructed a physical model of his theoretical design. However, his idea inspired many other inventors. The Scottish inventor John Logie Baird (1888–1945), for example, unveiled his mechanical disk design to the public in 1925. At that time, Baird's television technology was able to transmit and

receive crude patterns of light and dark to represent images. By 1929, Baird's improvements to image quality were so great that the British Broadcasting Corporation (BBC), a major European radio company, allowed him to conduct experiments using its transmitters. American inventor Charles Francis Jenkins (1867–1934) also based his work on Nipkow's design.

After several years of development, Jenkins received the first American television broadcasting license from the Federal Radio Commission in 1928, which allowed him to conduct experimental transmissions in Washington, D.C. Two years later, Jenkins rolled out his television for sale to the public. Jenkins's low-definition set had a 2 x 1.5-inch (5.08 x 3.81 cm) viewing screen with only 48 horizontal imaging lines. Independent inventors like Baird, Jenkins, and others were soon outmatched by groups of scientists employed by big corporations—including General Electric (GE), American Telephone & Telegraph (AT&T), and Radio Corporation of America (RCA)—who quickly churned out mechanical televisions. Television sales got off to a slow start, mostly due to a shortage of available television programming and broadcasting.

The need to fill television airtime created opportunities for aspiring actors and some famous radio actors who capitalized on the situation by moving to the new medium. Radio sponsors were captivated by the ability to advertise their products with both sound and images on television. For this reason, many entrepreneurs believed that the new medium had great potential.

Mechanical television technology received competition from a revival of earlier television technology. Since the early 1900s, several scientists had theorized about and experimented with electrochromic television technology, which employed a transmitting tube to project images onto a photosensitive array and then displayed them through a modified cathode ray tube. Russian scientist Vladimir Zworykin (1889–1982) secured corporate financial backing to make this technology a viable consumer product. In 1919, Zworykin emigrated to the United States and developed the iconoscope system while he worked for Westinghouse and later for RCA.

American independent inventor Philo Farnsworth (1906–1971), who has been credited as the inventor of

electric television, developed his own “improved” version of the electronic television system and held a public demonstration of his image-dissector tube system in 1934. However, sales of Farnsworth's set paled in comparison to Zworykin's RCA-backed machine. Mechanical and electronic television sets required broadcasts tailored to their exclusive designs. Rather than send two different kinds of broadcasts, Britain switched its broadcasting to electronic in 1936. The standardized broadcast signal convinced many British citizens to purchase electronic sets. However, just as the British television industry was gaining momentum, the BBC stopped all television broadcasts after the outbreak of World War II (1939–1945).

Before the war, Germany utilized television technology for the purpose of propaganda that promoted the idea of superiority. The 1936 Olympics held in Berlin was the first to be televised. The grandeur of the event on display for the world to see influenced the way all future Olympics were staged. Electronic televisions sported a larger screen and clearer image reproduction than did mechanical televisions. For these reasons, electronic televisions quickly gained in popularity over mechanical televisions by the mid-1930s in the United States.

The last recorded broadcast of a mechanical television signal was to a small remaining market in 1939. Even though electronic televisions had become the standard by the late 1930s, each U.S. corporation produced unique electronic television sets that required specialized broadcasts. Some American consumers remained hesitant to invest in any particular brand of television set for fear that it might become obsolete by a standardization of the broadcast signal. In 1941, the Federal Communications Commission (FCC) passed standards that insured the compatibility of all new television receivers with all television broadcast signals. However, American entrance into World War II in December of that year stagnated developments in the American television industry for the next four years.

After the war, the popularity of television eclipsed the popularity of radio. The number of television stations exploded. In fact, so many new television stations were created that in 1948, the FCC was forced to freeze the assignment of new station assignments because the clutter of new stations was creating

interference. It took the FCC four years to research, plan, and carry out new station assignments. After the FCC lifted the freeze in 1952, the flow of new stations started up once again.

Another conflict related to color broadcasting arose in 1949 between Columbia Broadcasting System's (CBS) field-sequential color system and RCA's dot-sequential color system, which were incompatible. After four years of hearings, the FCC mandated dot sequential as the standard color broadcasting system. In spite of the station assignment freeze and the color controversy, American television set sales continued to rise from 16,000 in 1947 to 4 million in 1949 to 11 million in 1950.

By the 1950s, television was the most popular household item. Television viewers were captivated by various forms of programs, including game shows, variety shows, serial dramas, and situation comedies. The *I Love Lucy Show* (1951–1957) was the decade's most popular comedy. In a time before technology to record programs was available to the public, viewers had to tune in if they wanted to see for themselves what funny situation the character of Lucy Ricardo (played by comedian Lucille Ball) would get herself involved in each week. In some cities, retail stores routinely closed early during the show's broadcast due to lack of customers. In large cities, the crime rate fell during the show's half-hour slot.

Television had a great influence on American daily life and culture. Advertisers influenced American choices in many aspects of life, including food, dress, cars, and music. Many teenagers tuned in to *American Bandstand* to learn the latest dance steps and to listen to the latest music. With allowances in hand, they would then rush to stores to buy records of the week's hit songs. The practice created a market for performers like Elvis Presley in the 1950s and the Beatles in the 1960s.

By the mid-1960s, the sale of color television sets outnumbered the sale of black-and-white sets. By that time, color broadcasting had become routine and about 9 out of 10 households had at least a black-and-white or color set. Besides the main driving force of the entertainment value of television, viewers also relied heavily on television news and other information. Throughout his career, television reporter Walter

Cronkite (1916–2009) gained respect and trust from many viewers.

In the 1950s, Senator Joseph McCarthy gained great political influence when he launched a witch hunt against people he claimed were communists who had infiltrated the U.S. government. During the so-called Second Red Scare, television reporter Edward R. Murrow exposed McCarthy as a fraud and helped destroy his reign of fear. During the first televised presidential debate between Richard Nixon and John F. Kennedy in 1960, the majority of television viewers reported that Kennedy had won the debate while those who listened to the same debate on the radio believed that Nixon had done better. Some historians pondered whether the homely Abraham Lincoln (1809–1865), who has been ranked by several polls as the best American president, would have been elected if he had lived during the television age. Political scientists wrote about the new visual dimension that television had forever introduced into politics. From that moment on, how a politician looked and how he or she moved would play a major role in who people voted for. Television technology also allowed people to view historic events as they happened. For example, in 1969, viewers witnessed the moon landing, and in 1989, they saw the fall of the Berlin wall.

Antennas wired to home television receivers had been the exclusive norm for most of television's history, but during the late 1970s, home satellite receivers had also appeared in some homes. By the 1980s, the three most powerful television networks were CBS, the National Broadcasting Company (NBC), and the American Broadcasting Company (ABC). In 1983, the final episode of *M*A*S*H* was seen on CBS by the highest recorded television audience in history of 125 million (77 percent of the audience share). Since 1967, the Public Broadcasting System (PBS) has offered viewers publicly supported alternative choices of programming in education, British dramas, and news. In the 1980s, cable companies, which sent signals to homes through coaxial cable from a central station antenna, also offered paying subscribers premium viewing choices.

In 1996, American broadcasters began displaying ratings of programs (such as TV-G for “general audiences,” TV-PG for “parental guidance suggested,”

TV-14 for “unsuitable for children under 14,” and TV-MA for “mature audiences only”). CBS and ABC also added V (violence), S (sex), L (coarse language), and D (suggestive dialogue) to their rating systems. Based on these rating systems, some television manufacturers imbedded a “V-chip” to allow parents to block programs they deemed inappropriate.

Standard-definition television screens typically had about 600 horizontal lines of dots (pixels). In recent years, the American government mandated a migration of all television broadcasting and receivers from analog to digital signal format, which delivered content in much sharper and clearer resolution. Plasma and liquid crystal display (LCD) television sets were made without cathode ray tubes. The lack of a tube enabled manufacturers to design thinner (or flat) screens for these televisions, which could be mounted on walls. These tubeless television screens contained electronically charged ions and electrons that bumped into one another when an electrical signal was introduced. The bumping created photons (glowing lights) that created screen images.

Manufacturers also rolled out big-screen, high-definition (HD) advanced television (ATV) sets, as well as sets that displayed three-dimensional images, capable of wireless convergence between computers and Internet content. By the 2000s, some HD sets contained 1080 x 500 pixels. The added pixels produced visually rich (almost lifelike) images. America’s love of television has not waned since its introduction. In 2005, the average American spent from two to five hours each day watching television.

Tennessee Valley Authority Electricity Project (TVA)

The Tennessee Valley Authority Electricity Project, also known as the TVA, is a federally owned U.S. corporation chartered through the TVA Act on May 18, 1933. Signed off on by President Franklin Delano Roosevelt, fervently backed by Nebraska senator George Norris, and inspired as a solution to the economic woes of the Great Depression, the TVA was created in alignment with the New Deal with the purpose of controlling floods along the Tennessee River, electric power generation, navigation, reforestation, prevention of soil erosion, and modernization of the greater general region. The corporation’s goal, in terms of power generation, was clear. It aimed to provide a reliable stream of electricity at wholesale rates to its customers. The corporation would also serve as a model in which privately owned utility companies could be measured and judged for their effectiveness and competitiveness in the market.

Upon its initial formation, the TVA obtained the Wilson Dam located in Muscle Shoals, a newly incorporated town in Alabama and perfectly positioned along the Tennessee River. Wilson Dam would serve as the TVA’s primary source of power generation during the corporation’s early development. But electricity was scarcely needed within the vicinity of Wilson Dam, which prompted the TVA to look for other markets to sell to.

The TVA was able to successfully generate the bulk of its first few years of income by acquiring transmission and distribution facilities from the Mississippi Power Company to sell to the Alabama Power Company. Between July 1934 and February 1935, the TVA sold \$294,712 worth of electricity. A new fleet of hydroelectric generating stations, including Norris, Wheeler, and Pickwick Landing Dams, were under construction and due to open before the start of the 1940s.

The Second World War further stimulated a need for power production to manufacture weapons and planes. The aluminum industry and Oak Ridge National Laboratory placed a large need for power on the TVA. In response, 12 hydroelectric plants and one steam plant were readily constructed, thus supplying

the energy necessary to meet these demands. TVA's cheap electric rates made the Tennessee Valley a fertile location for industrial growth. This strengthened the economic climate of the region as more jobs became available, drawing larger populations and new businesses. Due to the construction of TVA's new facilities alone, roughly 28,000 jobs were created.

By the 1950s, the TVA had become the largest supplier of electricity in the United States. The region continued to see growth even after the war ended. No longer capable of meeting the demand for electricity, the TVA looked to coal-fired steam plants as a solution. This marked an important period for the TVA as it successfully sought financial independence, allowing it to issue bonds to build and obtain more plants. It not only bought a few coal-fired plants from utility companies but had begun constructing its own as early as 1942, with the Watts Bar Steam Plant being the first. Watts Bar was capable of generating 267 MW, but that wasn't enough. In total, the TVA built seven coal-fired plants, predominantly in Tennessee and Alabama, during the 1950s that together produced over 3,770 MW of power. The Widows Creek Fossil Plant's Unit 7 was generating an impressive 500 MW of power, at the time the largest of its kind in the world.

In 1966, TVA sought to continue its expansion of electric generating stations by constructing its first nuclear generating plant—Browns Ferry, near Athens, Alabama. Browns Ferry Plant made world history with its three boiling reactors producing over 1 billion watts of power by 1976. Plans had initially called for several more nuclear stations, but the oil embargo of 1973 caused electricity rates within the TVA to skyrocket as much as five times higher than its normal rate.

The TVA went through a drastic period of restructuring its organization, which led to the cancelation of many nuclear construction projects. After successfully rebounding from the effects of the oil crisis, the federal corporation soon began to focus on clean energy and economic development. In 2000, it launched the Green Power Switch program, a program dedicated to introducing more renewable energy into the electric grid. In 2011, the TVA, in agreement with the Environmental Protection Agency (EPA), committed to retiring 18 of its 59 coal-fired plants by 2017. Between

2005 and 2013, TVA reduced 32 percent of its carbon dioxide emissions.

As of 2017, the TVA stands as the United States' largest government-owned power provider. In 2016, the revenue produced by its power production and distribution reached approximately \$10.5 billion. The TVA receives no tax dollars, and its profit is reinvested into providing better quality power production as well as into community development programs. The TVA boasts a wide range of production facilities, including 29 hydro plants, 14 solar energy sites, 9 natural-gas-combustion turbine plants, 8 fossil plants, 7 natural gas combined-cycle plants, 3 nuclear plants, 1 pumped-storage hydroelectric plant, 1 diesel-generator site, and 1 wind-energy site. Its energy production is capable of 169,000 gigawatt-hours. Of this energy produced, 37 percent comes from nuclear, 24 percent coal, 20 percent natural gas, 9 percent hydro, 3 percent wind and solar, and 7 percent energy efficiency.

Jonathan G. Herrera

Thomas, Vivien Theodore (1910–1985)

Vivien Theodore Thomas was an African American laboratory technician; educational instructor at Johns Hopkins University, Baltimore; and an innovator of cardiac surgery. His most notable recognitions include contribution to the discovery of the cause of traumatic shock and developing the procedure for and guiding the first operation to treat tetralogy of Fallot, commonly

known as the “blue baby syndrome” responsible for the deaths of thousands of children every year. Other accomplishments include aiding in the development of the electrical defibrillator and executing the first atrial septectomy.

Thomas was born the grandson of a slave on August 29, 1910, in New Iberia, Louisiana. In his early years, Thomas worked as a carpenter alongside his father. At age 19, he graduated with honors from Pearl High School in Nashville, Tennessee. He then began to pursue his dream of becoming a doctor and enrolled in a premedical course at the Tennessee State Agricultural and Industrial College in Nashville. Due to the financial hardships brought on by the Great Depression, Thomas was forced to put his college career on hold and seek employment.

On February 10, 1930, Thomas applied for a laboratory assistant position at Vanderbilt University Medical School. At Vanderbilt, he was introduced to Dr. Alfred Blalock, his mentor and employer. This marked the beginning of a partnership that achieved medical and scientific breakthroughs. From the beginning, Thomas immersed himself in the studies of Blalock’s research, countless textbooks, and learned anatomy from Dr. Joseph Beard (1901–1983). Thomas would often work late hours with Blalock, and they would share each other’s findings and research as well as enjoy alcoholic beverages together, which was not acceptable to society at the time due to Thomas’s African American background.

In 1933, Blalock presented his theory of traumatic shock to the Chicago Surgical Society that had been developed in his experiments with Thomas. Traumatic shock was the leading cause of death in surgical procedures. Their theory claimed that one of its major causes was blood loss. Blalock and Thomas had an unparalleled partnership. In 1937, Blalock rejected an offer of employment at Henry Ford Hospital in Detroit because it did not permit African American employees.

In 1943, Dr. Helen Taussig, who was one of the first recognized female pediatric cardiologists, reached out to Blalock for a surgical solution to the tetralogy of Fallot/blue baby syndrome. With Thomas’s assistance, they were able to draft the first procedure to treat blue baby syndrome. Blalock and Thomas executed its first-ever operation on Eileen Saxon (1942–1945), one

of Taussig’s patients who was in extremely critical condition. The operation was successful and extended Eileen Saxon’s life past previous expectancy, but unfortunately, she died less than a year later.

More operations were conducted shortly afterward, which brought great fame and recognition to Blalock and Taussig for their surgical breakthrough. In today’s operation, a similar tool called the “Blalock clamp” is used. This surgical breakthrough has saved millions of lives since its original discovery, which wouldn’t have been possible without the assistance of Thomas’s research.

These discoveries in blue baby syndrome solutions brought fame and recognition to Johns Hopkins University. It became Vivien Thomas’s unofficial responsibility to instruct in surgery at the university; he taught students surgical procedures that contributed to the newly developed field of cardiac and cardiovascular surgery.

Thirty years after Thomas first entered the doors of Johns Hopkins University, a portrait of him was commissioned to recognize his achievements, the first portrait of an African American to be hung in the university’s halls. It was displayed alongside those of the university’s presidents and professors.

On May 21, 1976, Thomas received an honorary doctorate from Johns Hopkins University. In the following year, he was officially appointed to the faculty of Johns Hopkins and granted the position of instructor of surgery.

Thomas served as an African American icon and leader in the Johns Hopkins community. His students Richard Scott (1941–present) and Levi Watkins (1944–present) became the university’s first official black surgical resident and first black cardiac resident. Thomas’s final research project was conducted alongside his apprentice, Levi Watkins, which led to the first human implantation of the automatic implantable defibrillator.

Tizard Mission

The Tizard Mission was the informal name given to a British delegation that came to the United States in 1940 seeking support for the development of British technical innovations. Britain hoped to exploit British innovations in the war against Germany and Italy. Formally known as the British Technical and Scientific Mission, the mission became known as the Tizard Mission after Henry Tizard, the man who organized the endeavor.

While the United States formally declared war in December 1941, England had gone to war against Axis powers in 1939. The United States had officially been neutral between 1939 and 1941, but President Franklin D. Roosevelt and other leaders in the federal government were not averse to helping England. To this end, a British delegation came to the United States in September 1940. The mission shared British technological innovations, including radar, jet engine improvements, and atom bomb science.

Because many members of the U.S. Congress opposed overt cooperation with the British, fearing a breach in American neutrality, Tizard shared technological information with American scientist Archibald Hill, who then advocated for the mission in Washington.

Mission members included representatives of the British Army, Royal Navy, Royal Airforce, Army Research, and a scientist specializing in radar. Members of the mission toured General Electric Labs, met with Enrico Fermi at Columbia University and members of the U.S. Army, including General "Hap" Arnold, who would oversee the Women Airforce Service Pilots (WASPs) from 1942 to 1944.

Though the Tizard Mission is now considered a success, Henry Tizard returned to London to find that his job no longer existed. After the war, he would lead

a research project into the existence of unidentified flying objects (UFOs).

Women's Airforce Service Pilots (WASPs)

The energetic and enthusiastic work of two dedicated female pilots, Jacqueline Cochran and Nancy Harkness Love, resulted in the formation of the Women's Airforce Service Pilots (WASPs), the first group of military-sanctioned female pilots in the United States.

In September 1939, Cochran wrote a letter to Eleanor Roosevelt declaring that with the war in Europe (World War II) going badly, America should begin allowing women to fly noncombat missions to free the men for overseas duty. She received a polite and supportive response from the first lady but knew that the decision would not be up to her. In May 1940, a similar letter was sent to the U.S. Army Air Corps, Plans Division, by Love. Her letter also met with inaction.

In 1941 Cochran met with General H. H. "Hap" Arnold, chief of the U.S. Army Air Corps, and again put forth her idea. Something similar was already underway in England with the Air Transport Authority (ATA), which was taking volunteers from all countries. Arnold recommended that Cochran work with the ATA to help show the American military that women ferry pilots were a good idea. For the ATA, Cochran agreed to ferry a bomber plane from its manufacture site in North America to its base in England. After she successfully completed the mission, the U.S. government was still not convinced that its military

could benefit from such a group. Cochran put her efforts toward recruiting American female pilots for the British ATA.

On May 28, 1941, Congresswoman Edith Nourse Rogers proposed to Congress the legislation that would establish a Women's Army Auxiliary Corps (WAAC). It was stalled in Congress until after the bombing of Pearl Harbor and then was debated until the U.S. Air Force showed an interest in using the services of qualified women pilots. The bill was passed on May 15, 1942, nearly a year after it was proposed.

Love, who had moved to Washington, D.C., when her husband was called to military duty, met with his superiors at the Air Transport Command (ATC) to reintroduce the concept of women ferry pilots. The new commander, Brigadier General Harold L. George, asked Love to draft a proposal. On September 10, 1942, Love's proposal was announced in the newspapers. Women who filled the requirements were asked to apply to what was then called the Women's Auxiliary Ferrying Squadron (WAFS). Requirements for applicants included two letters of recommendation, a high school degree, and 500 hours of logged flying time. While male pilots could be between the ages of 19 and 45, female applicants had to be between the ages of 21 and 35.

When Cochran returned from her recruitment efforts for the British ATA, she was astounded to learn that an American group had been created without her. General Arnold made her the director of the Women's Flying Training Detachment (WFTD), a group organized to train novice women pilots to fulfill WAFS requirements.

In July 1943, the Pentagon combined the WAFS and the WFTD, creating the WASP. To support its efforts, Walt Disney created *Fifinella*, a female gremlin mascot for the group.

After the merger, Cochran was promoted to director of women pilots. Through her efforts, the WASP ferried larger aircraft and took positions towing targets for bombers. They also flew as check pilots on planes reported faulty by male pilots, leading to some of the few fatalities associated with the WASP program.

In February 1944, H.R. 4219 was presented in Congress to militarize the WASP and provide all the benefits of soldiers, from free uniforms to postwar

pensions. This drew angry letter-writing campaigns from male pilots who had failed to pass military tests and physicals. They wanted the duties of the WASPs to be handed to them, even though WASPs were better-qualified pilots. These complaints were considered by the House Committee of Military Affairs in March 1944 along with testimony by only one witness, General Arnold. The vote was 169 to 188. H.R. 4219 was killed in Congress on June 21, 1944.

At this time, the WASP program was also cut, allowing female pilots already in service to continue through the end of the war but denying any further training to women for the purpose of entering the WASP. A new class of trainees already en route to Avenger Field had to be sent home when they arrived. As the war in Europe seemed to be going well for the Allies, the WASP program was deactivated on December 20, 1944. There had been 1,074 female pilots in the WASP program and 38 fatalities.

In 1953, the military recalled interested former WASPs to their old posts to provide support during the Korean War.

In September 1976, the U.S. Senate finally voted to make the WASPs official veterans of World War II, partly as a result of lobbying by the WASP alumni group known as the Order of *Fifinella*. In their deactivation letters, General Arnold wrote to the WASPs, "When we needed you, you came through and have served most commendably under very difficult circumstances."

Perhaps the feel of being a WASP was best expressed by Cornelia Fort, who died on duty with the WASP. Before she died, she wrote,

As long as our planes fly overhead the skies of America are free and that's what all of us everywhere are fighting for. And that we, in a very small way, are being allowed to help keep that sky free is the most beautiful thing I have ever known. I, for one, am profoundly grateful that my one talent, my only knowledge, flying, happens to be of use to my country when it is needed. That's all the luck I ever hope to have.

Wu, Chien-Shiung (1912–1997)

Distinguished Chinese American experimental physicist and the “First Lady of Physics,” Chien-Shiung Wu is best known for the Wu experiment, which proved that the law of conservation of parity does not hold for weak subatomic interactions. Dr. Wu was an expert in the subject of beta decay and played an important role in the Manhattan Project.

Chien-Shiung Wu was born to Chinese parents: Zhong-Yi Wu, her father, and Funhua Fan, her mother, on May 31, 1912, in Liuhe, Taicang, Jiangsu Province, China. Her father was an engineer by training and strongly believed in equality for women. In 1913, he founded one of the first schools in China to admit girls. Wu attended her father’s school, where she showed great promise in math and science. When she was 11 years old, she left home to attend the Suzhou Women’s Normal School No. 2. Wu borrowed mathematics, physics, and chemistry books from her friends who attended the regular school program and read and studied from them at night. She graduated at the top of her class in 1929. In 1934, she received a BS degree in physics from the National Central University (NCU) in Nanjing. She taught for one year at the Zhejiang University and did two years of graduate-level study in physics as an assistant at the Academia Sinica.

In 1936, Wu took a ship to the United States with her friend Dong Ruofen. The two women arrived in San Francisco, California, and visited the University of California, Berkeley. There, Wu met physicist Ernest Orlando Lawrence, inventor of the cyclotron particle accelerator. Lawrence convinced her to attend UC Berkeley, where she would complete her PhD in physics in 1940.

In 1942, Wu married physicist Luke Chia-Liu Yuan, grandson of the first president of the new

The “First Lady of Physics,” Chien-Shiung Wu developed the process for separating uranium for the Manhattan Project to produce the first nuclear bombs. She won a Nobel Prize in physics in 1957. (Library of Congress)

Republic of China. She met Yuan at Berkeley, and it was he who convinced her to do her graduate studies there. They would have one son, Vincent Yuan, who also became a physicist. Also in 1942, Smith College offered Wu a teaching position. Smith did not have a research facility, and in 1943, Wu accepted an offer from Princeton University. She was invited to join the Manhattan District Project (Manhattan Project) at Columbia University as a senior scientist in 1944. As a Manhattan Project researcher, she developed a process that separated uranium metal into the U-235 and U-238 isotopes by gaseous diffusion. Wu’s work helped with the development of the atomic bomb.

Wu worked at the Physics Department at Columbia University until 1981, when she retired as a Michael I. Pupin Emerita Professor of Physics. In the mid-1950s, Tsung-Dao Lee and Chen-Ning Yang agreed that the law of conservation of parity had not been tested for weak nuclear force and theorized that it would not hold true for that type of subatomic

interaction. For her expertise in beta decay (she published a book titled *Beta Decay* in 1965), they asked Wu to assist them. They proved that the law of conservation of parity did not hold true for the weak nuclear force. In 1957, Lee and Yang were awarded the Nobel Prize in Physics. The Nobel Prize committee did not recognize Wu's work. However, in 1978, she received the first Wolf Prize in Physics for her experimental work on the law of conservation of parity. Wu's research included the correlation of the quantum polarizations of two photons that propagate in opposite directions, the molecular changes in the deformation of hemoglobin that cause sickle-cell disease, and work on the Mossbauer effect. She won the National Medal of Science in 1975. After her retirement in 1981, Wu devoted her time and effort to educational programs to promote female scientists, in part because of her own

struggles for recognition as a woman scientist. Wu died in New York in 1997 from a stroke and was buried in China. She is remembered as the "Queen of Nuclear Research" and the "First Lady of Physics" for her significant contributions to American science.

Contents

VOLUME 1: COLONIAL AMERICA TO 1865

Introduction, xxi

Chronology, xxvii

Section 1: Colonial America and Enlightenment Science, 1

Overview, 1

American Philosophical Society, 8

Primary Document: Memorial of the American Philosophical Society Favoring an Exploration of the Alaskan Coast (1868), 10

Astronomical Almanacs, 11

Primary Document: Aphorisms from *Poor Richard's Almanack* (1732–1758), 13

Banneker, Benjamin (1731–1806), 13

Primary Document: Letter of Thomas Jefferson to Benjamin Banneker, Expressing Jefferson's Belief That Blacks Had Talents Equal to Other Races (1791), 14

Primary Document: Frontispiece of Benjamin Banneker's *Pennsylvania, Delaware, Maryland and Virginia Almanack and Ephemeris* (1792), 15

Bifocals, 16

Primary Document: Benjamin Franklin's Letter Describing His Invention of Bifocals (1725), 17

Bushnell, David (1740–c. 1824), 17

Primary Document: Engraving of David Bushnell's *American Turtle* (1775), 18

Colden, Jane (1724–1766), 19

Daylight Saving Time, 20

Extension Arm (Long Arm), 21

Fire Safety, 21

Flexible Catheter, 22

Food Production, Native American, 23

Franklin, Benjamin (1706–1790), 25

Primary Document: Letter of Benjamin Franklin Describing His Experiments with Electricity (c. 1750), 26

Franklin Stove, 27

Primary Document: Excerpt from Benjamin Franklin's *An Account of the New Invented Pennsylvanian Fire-Places* (1744), 28

Glass Harmonica (Armonica), 30

Primary Document: Excerpt of Benjamin Franklin's Letter to Father Giambatista Beccaria Describing the Glass Harmonica (1762), 32

Glover, Elizabeth (d. 1643), 32

Godfrey, Thomas (1704–1749), 33

Iron- and Silversmithing, 34

Kentucky Long Rifle, 35

Lightning Rod, 36

Primary Document: Frontispiece and Title Page of Benjamin Franklin’s *Experiments and Observations on Electricity* (1774), 37

Loom, 38

Primary Document: Excerpts from the Diary of Martha Ballard Describing Home Weaving (1787), 39

Lucas, Eliza (1722–1793), 40

Primary Document: Letter of Eliza Lucas to Her Father (1741), 41

Masters, Sybilla (c. 1675–1720), 42

Mather, Cotton (1663–1728), 43

Natural History, 44

Onesimus (fl. 1706–1716), 46

Peale, Charles Willson (1741–1827), 47

Primary Document: Letter of Charles Willson Peale to Thomas Jefferson Regarding New Agricultural Inventions and Innovations (1815), 48

Priestley, Joseph (1733–1804), 51

Rittenhouse, David (1732–1796), 52

Primary Document: Letter of Thomas Jefferson to David Rittenhouse (1778), 53

“Saugus Pot,” 54

Schooner, 55

Smallpox Inoculation, 56

Primary Document: George Washington’s Order for All Soldiers to Receive a Smallpox Inoculation (1778) and Letter of Edward Rowse to Thomas Jefferson Suggesting the Possibility of Vaccines for Other Diseases (1805), 58

Spinning Wheel, 59

Primary Document: An “Address to the Ladies” Urging American Women to Boycott British Goods (1767), 61

Street Lighting, 62

Swim Fins, 62

Three-Wheel Clock, 63

Primary Document: James Ferguson’s Description of Benjamin Franklin’s Three-Wheel Clock (1773), 64

Turtle Submarine, 65

Primary Document: Letter of David Bushnell to Thomas Jefferson Regarding Bushnell’s Experiments with Submarines (1787), 66

Whiton, David Erskine (1825–1904), 67

Winthrop, John (1714–1779), 68

Primary Document: John Winthrop Describes His Observation of the Planet Venus (1761), 69

Section 2: The New Republic and the Market Economy (1780–1820), 71

Overview, 71

Amphibious Steam Vehicle, 79

Primary Document: Image of an Amphibious Steam Vehicle (1834), 81

Apple Parers, 82

Primary Document: Apple Parer Patent Document Image (1836), 83

Babbitt, Sarah “Tabitha” (1779–1853), 84

Ballard, Martha (1735–1812), 84

Banjo Clock, 87

Blackwell, Elizabeth (1821–1910), 87

Primary Document: Excerpts from “Address on the Medical Education of Women” by Elizabeth and Emily Blackwell (1863), 89

Burr Truss Bridge, 91

Canals, 92

Canning Factory, 95

Charting the Gulf Stream, 96

Circular Saw, 97

Coffee Percolator, 98

- Cotton Gin, 99
- Cotton Sewing Thread, 101
- Dental Floss, 102
- Diffraction Grating, 103
- Erie Canal, 104
 - Primary Document: Letter of Robert Fulton to George Washington Urging Him to Support the Construction of Canals (1797), 106
- Evans, Oliver (1755–1819), 107
 - Primary Document: Letters from Oliver Evans to Thomas Jefferson (1804, 1808), 108
- Fire Hydrant, 109
 - Primary Document: Account of the Detroit Fire (1805), 110
- Fitch, John (1743–1798), 111
- Flatboat, 112
- Fulton, Robert (1765–1815), 114
- Gas Tungsten Arc Welding, 115
- Greene, Catharine Littlefield (1755–1814), 116
- High-Pressure Steam Engine, 117
- Interchangeable Parts, 118
- Internal Combustion Engine, 119
- Jefferson, Thomas (1743–1826), 121
- Lewis and Clark Expedition (1804–1806), 123
 - Primary Document: Excerpts from the Journal of the Lewis and Clark Expedition (1805, 1806), 126
- Lobster Trap, 127
- Lowell Mill System, 128
 - Primary Document: Description of the Life of a Mill Girl from the Lowell Offering (1845), 129
- Milling Machine, 130
- Morey, Samuel (1762–1843), 131
- Multitubular Boiler, 132
- National Road, 132
- Odometer, 135
- Patent and Copyright Statutes, 135
- Practical Ocean Navigation, 137
- Report on Manufactures* (1791), 138
- River Steamer, 139
- Rumford Fireplace, 141
- Rush, Benjamin (1746–1813), 142
 - Primary Document: Excerpt from the Medical Writings of Benjamin Rush (1805), 144
- Screw-Cutting Lathe, 145
- Slater, Samuel (1768–1835), 146
- Steam Engine, 148
- Steam Tractor, 149
- Steamboat, 150
 - Primary Document: Newspaper Announcement of Robert Fulton’s Steamboat (1807) and Charles Dickens’s Account of His Ride on an American Steamboat (1842), 153
- Submarine, 154
- Suspension Bridge, 155
- Swivel Chair, 157
- Thompson, Benjamin (Count Rumford) (1753–1814), 158
- Three-Piece Iron Plow, 159
 - Primary Document: Petition to Congress Asking for a Renewal of the Patent on Jethro Wood’s Cast-Iron Plow (1846), 160
- Vapor-Compression Refrigerator, 161
- Waltham-Lowell Textile System, 161
- Wheel Cipher, 162
 - Primary Document: Excerpts from Thomas Jefferson’s Notes on the Wheel Cipher (Undated), 163
- Whitney, Eli (1765–1825), 163
 - Primary Document: Letter of Eli Whitney to His Father Regarding the Ginning of Cotton (1793), 165

Section 3: Antebellum Industrialization and the Civil War (1820–1865), 167

Overview, 167

Adhesive Tape, 174

Agassiz, Louis (1807–1873), 175

Primary Document: Excerpt from the Journal of Louis Agassiz Describing a Trip to the United States (1846), 176

Anesthesia, 178

Ball Bearings and Babbitt Metal, 179

Best Friend Steam Engine, 181

Breast Pump, 182

Brown Truss, 182

Burglar Alarm, 183

Calliope (Steam Organ), 183

Cannon, Double-Barrel, 185

Primary Document: Excerpt from the Memoirs of Former Confederate General Edward Porter Alexander on “Artillery Hell” at Antietam (1907), 186

Civil War Medicine (1861–1865), 186

Primary Document: Report of Medical Director Robert Murray on Union Casualties Suffered at the Battle of Shiloh (1862), 188

Civil War Nursing, 190

Primary Document: Clara Barton’s Poem “The Women Who Went to the Field” (1892), 192

Clipper Ship, 194

Primary Document: Excerpts from the Journal of Alexander Van Valen Describing His Journey to California via Clipper Ship (1849), 196

Clothespin, 196

Coal-Mining Technologies, 197

Coil Magnet/Electromagnet, 199

Colgate, William (1783–1857), 200

Colored Female Free Produce Society, 201

Colt, Samuel (1814–1862), 202

Colt Revolver, 203

Columbiad Cannon, 204

Combine Harvester, 205

Compact Iron Stove, 207

Conestoga Wagon, 208

Primary Document: Excerpt from John G. Abbott’s Recollections of Traveling to California by Wagon Train (1852), 210

Corn Sheller, 211

Corset, 211

Coston, Martha (1826–1904), 213

Cowboy Hat (Stetson), 213

Crumpler, Rebecca (1831–1895), 214

Cylinder Pin Tumbler Lock, 216

Dahlgren Gun, 216

Deere, John (1804–1886) and Deere and Company, 217

Dental Chair, 219

Detachable Collar, 219

Dix, Dorothea (1802–1887), 220

Dustpan, 221

Eggbeater, 222

Electric Doorbell, 223

Electric Stove, 223

Electric Street Railway, 223

Elevator Safety Brake, 224

Equatorial Sextant, 225

Field, Cyrus West (1819–1892), 226

Fire Alarm Call Box, 227

Floating Dry Dock (1849), 228

Primary Document: Excerpt from Abraham Lincoln’s Patent Application for the Floating Dry Dock (1849), 229

Gas Well, 230

Gold-Mining Technologies, 231

Goodyear, Charles (1800–1860), 232

- Grain Elevator, 233
- Gridiron for Cooking, 234
- Hand-Cranked Ice Cream Maker, 234
- Health Reform, 235
- Henry, Joseph (1797–1878), 237
- Hoop Skirt, 238
- Horse-Drawn Streetcar, 239
 - Primary Document: Image of a Horse-Drawn Streetcar (c. 1920), 240
- Hospital Transport Service, Women’s Department, 240
- Howe, Elias (1819–1867), 241
- Howe Truss, 242
- Interchangeable Gun Parts, 243
- Inverted Microscope, 244
- Jervis, John B. (1795–1885), 245
- Land Mines, 245
- Long, Crawford Williamson (1815–1878), 246
- Machine/Gatling Gun, 247
- Mason Jar, 249
- Maynard, Edward (1813–1891), 249
- Maynard Carbine, 250
- McCormick, Cyrus (1809–1884), 252
 - Primary Document: Letter of Robert E. Lee to Cyrus McCormick Regarding the Curriculum at Washington College (1865), 253
- Mechanical Reaper, 254
- Merrick, Solymon (1806–1852), 255
- Military Technology (Civil War), 255
- Mitchell, Maria (1818–1889), 258
- Morse, Samuel F. B. (1791–1872), 260
- Morse Code, 261
- National Academy of Sciences (NAS), 262
- Nightingale Plan, 263
- North, Simeon (1765–1852), 264
- Omnibus System, 265
- Papermaking Machine, 266
- Pencil Eraser, 267
- Pepper (and Salt) Shaker, 267
- Perkins, Jacob (1766–1849), 267
- Platform Scale, 268
- Polished Steel Plow, 269
- Printing, 269
- Printing Telegraph, 271
- Pullman, George Mortimer (1831–1897), 273
- Railroad T-Rail and Tie, 273
- Railroads, 274
 - Primary Document: Pacific Railway Act (1862), 276
- Ratchet Wrench, 279
- Relay, 280
- Repeating Rifle, 280
- Roller Skates, 282
- Rotary Hook (for Sewing Machines), 283
- Rucker Ambulance, 283
- Safety Pin, 284
- Sewing Machine, Automated, 284
- Sewing Pattern, 286
- Solar Compass, 287
- Spar Torpedo, 288
- Steam Locomotive, 288
- Steam Shovel, 291
- Stevens, Robert Livingston (1787–1856), 292
- Strauss, Levi (1829–1902), 294
- Telegraph, 294
 - Primary Document: Act Authorizing Construction of a Transcontinental Telegraph (1855), 297
- Ten-Hour Movement, 297
 - Primary Document: Excerpt from the Preamble and Constitution of the Lowell Female Labor Reform Association (1846), 298
- Toothpaste, 299

Torpedo, 301
 Transatlantic Cable, 302
 Transverse Shuttle, 303
 Twine Knotter, 304
 Twist Drill, 304
 United States Capitol Building, Construction of, 304
 U.S. Sanitary Commission (USSC), 306

Vulcanization, 307
 Walker, Mary (1832–1919), 308
 Western Union Telegraph Company, 310
 Zipper, 311
Bibliography: Colonial America to 1865, 313
Index, 317

VOLUME 2: RECONSTRUCTION THROUGH WORLD WAR II

Section 1: The Rise of Industrialism, Reconstruction, and the Gilded Age (1866–1900), 1

Overview, 1

Abbe, Cleveland (1838–1916), 7

AC Generator and Transformer, 9

Primary Document: American Institute of
 Electrical Engineers (AIEE) Member
 Biography for William Stanley (1934), 10

AC Induction Motor, 10

Primary Document: Nikola Tesla's Patent for an
 AC Induction Motor (1896), 11

Adding Machine with Keys, 14

Amalgamated Clothing Workers of America
 (ACWA), 14

American Telephone and Telegraph Company
 (AT&T), 16

Asphalt, 17

Aspirin, 18

Barbed Wire, 19

Primary Document: Excerpts from an Article on
 Joseph F. Glidden and the Barb-Wire
 Industry (1884), 21

Batteries, 23

Bee Smoker, 24

Primary Document: Excerpt on the Use of a Bee
 Smoker from Moses Quinby's *Mysteries of
 Bee-Keeping Explained* (1853), 24

Bell, Alexander Graham (1847–1922), 26

Primary Document: Letter of Alexander Graham
 Bell to His Parents Describing His Idea for
 the Telephone (1874), 27

Berliner, Emile (1851–1929), 29

Brooklyn Bridge, 30

Camera, 31

Can Opener, 33

Carnegie, Andrew (1836–1919), 34

Carnegie Steel Mill, 35

Primary Document: Correspondence of Andrew
 Carnegie and Henry Clay Frick Regarding
 the Homestead Strike (1892), 37

Carpet Sweeper, 38

Carver, George Washington (1861–1943), 38

Primary Document: George Washington Carver
 Addresses Congress (1921), 41

Cash Register, 42

Celluloid, 42

Coca-Cola, 43

Cotton Candy Machine, 45

Crayons, 45

Curling Iron, 47

Diner (Horse-Drawn), 47

Dishwashing Machine, 48

Dow Chemical Company, 49

- du Pont, Pierre (1870–1954), 50
- DuPont Company, 52
- Duprey, Ana Roqué de (1853–1933), 54
- Duryea, Charles (1861–1938) and Frank (1869–1967), 54
- Earmuffs, 55
- Eastman, George (1854–1932), 56
- Eastman Kodak Company, 56
- Edison, Thomas (1847–1931), 57
- Electric Iron, 59
- Electric Lightbulb, 60
- Electricity, War of the Currents, 61
- Electrification, Urban, 63
- Escalator, 65
- Ferris Wheel, 66
 - Primary Document: Telegrams between Luther Rice and George Ferris Following the Successful Test of the Ferris Wheel (1893), 68
- Folding Cabinet Bed, 68
 - Primary Document: Patent for Folding Cabinet Bed (1885), 69
- Food Preservation, 70
- Fountain Pen, 71
- Frasch Process, 72
- Gas Transmission, 73
- General Electric, 74
- Goodrich, B. F. (1841–1888), 75
- Goodyear, Charles, Jr. (1833–1896), 76
- Hallidie, Andrew Smith (1836–1900), 76
- Harvard Computers, 77
 - Primary Document: Undated Photo of the Harvard Computers, 79
- Haynes, Elwood (1857–1925), 79
- Heyl, Henry (1842–1919), 80
- Ice Cream Soda, 81
- Inman, George (1895–1972), 82
- Iron Ship with Revolving Turret, 83
- Ironing Board, 83
- Jeans, 84
- Jockstrap, 86
- Jones, Amanda T. (1835–1914), 86
 - Primary Document: “The Soldier’s Mother” by Amanda T. Jones (1867), 87
- Kellogg, William Keith (1860–1951), 88
- Kelly, William (1811–1888), 89
- Kier, Samuel (1813–1874), 90
- Kinematoscope, 91
- Knight, Margaret (1838–1914), 91
- Lady Stitchers’ Union, 92
- Lawn Mower, Reel-Type, 93
- Lennox, David (1855–1947), 93
- Linotype Machine, 94
- Margarine, 95
- Matchbook Matches, 96
- Matzeliger, Jan Ernst (1852–1889), 96
- Maxim, Hudson (1853–1927), 97
- Metal Detector, 97
- Metal Electrode Weld, 98
- Metal Windmill, 99
- Military Technology (Post–Civil War through World War I), 100
- Motion Picture Camera, 102
- National Consumers League, 104
- National Institutes of Health (NIH), 105
- Niagara Falls Power Plant, 106
 - Primary Document: Excerpt from Nikola Tesla’s Commemoration Address for the Niagara Falls Power Plant (1897), 108

Office Technology (Pre–World War II), 112

Paper Bag, 114

Paper Clip, 114

Phonograph, 115

Primary Document: Roll Call of Companies at
the Phonograph Convention in Chicago
(1890), 119

Photographic Film, 120

Pipe Wrench, 121

Player Piano, 121

Portland Cement Mortar, 122

Punch Card Tabulator, 123

Quadruplex Telegraph, 124

Railroad Refrigerator Car, 125

Railroad Sleeping Car and Pullman Car, 126

Railroad Switch Systems, 127

Richards, Ellen Swallow (1842–1911), 128

Roebing, Emily (1843–1903), 129

Primary Document: Photograph of the Promenade
on the Brooklyn Bridge (1899), 131

Roebing, John (1806–1869), 131

Roll Film, 133

Roller Coaster, 133

Rotary Washing Machine, 134

Rowing Machine, 135

Saccharine, 135

Silo, 137

Skyscraper, 138

Soda Fountain, 140

Spork, 141

Steel Arched Bridge, 142

Stethoscope, Binaural, 143

Stockyards, 144

Primary Document: Photograph of Chicago’s
Union Stock Yards (1907), 145

Tape Measure, 146

Taylor, Frederick (1856–1915), 146

Tesla, Nikola (1856–1943), 147

Ticker Tape, 149

Tom Thumb Locomotive, 150

Primary Document: John Latrobe’s Description
of the *Tom Thumb* Locomotive (1830), 150

Track-Type Tractor, 152

Transcontinental Railroad, 153

Twine Self-Binding Harvester, 155

Typewriter and QWERTY, 155

Velocipede, 156

Vending Machine, 157

Vibrator, 158

Water Heater, 159

Westinghouse Air Brake, 160

World’s Fairs, 161

Wright, Wilbur (1867–1912) and Orville
(1871–1948), 164

Primary Document: Entry from Orville Wright’s
Diary of December 17, 1903, 166

Yerkes Observatory, 166

Section 2: The Progressive Era and the Roaring Twenties (1900–1929), 169

Overview, 169

Aerosol Spray Can, 176

Airplane, 176

Anderson, Mary (1866–1953), 179

Assembly Line, 179

Primary Document: Excerpt from Henry Ford’s
“The First Assembly Line” (1913), 181

Automobile Technologies (Pre–World War II), 181

Bakelite, 183

Band-Aid, 185

Bell Telephone Laboratories, 185

- Binney & Smith Inc., 186
- Birdseye, Clarence (1886–1956), 187
- Blender, 188
- Blodgett, Katherine (1898–1979), 188
- Boeing, William E. (1881–1956), 189
- Bottle-Making Machine, 190
- Bread Slicer and Wrapping Machine, 191
- Bryant, Alice (1862–1942), 192
- Cannon, Annie Jump (1863–1941), 192
- Carothers, Wallace (1896–1937), 194
- Christmas Tree Lights, 194
- Chuck Wagon, 195
- de Forest, Lee (1873–1961), 196
- Dickelman, Elizabeth (dates unknown), 197
- Dickerson, Mary Cynthia (1866–1923), 197
- Drew, Charles (1904–1950), 198
- Ductile Tungsten, 199
- Einstein, Albert (1879–1955), 199
- Empire State Building, 201
- Ford, Henry (1863–1947), 202
- Freon, 204
- Galvin, Paul Vincent (1895–1959), 205
- General Motors (GM), 206
- Gilbreth, Lillian (1878–1972), 208
- Gramophone/Victrola, 208
- Gumball Machine, 210
- Hewitt, Peter C. (1861–1921), 210
- Hoosier Cabinet, 212
- Hydroelectric Power, 212
- Jacob, Mary Phelps (1891–1970), 214
- Kettering, Charles F. (1876–1958), 215
- Lie Detector, 216
- Life Savers Candy, 217
- Marsh, Albert L. (1877–1944), 217
- McKnight, William L. (1887–1978), 218
- Midgley, Thomas (1889–1944), 219

- Triode Tube, 246
- Turbine Engine, Gas Powered, 247
- Washing Machine, Electric, 247
- Welding, Alternating Current, 248
- Welding, Automatic, 249

Section 3: The Great Depression and World War II (1930–1945), 251

Overview, 251

Alaska Highway, 257

Primary Document: Excerpt from Ruth Gruber’s Study of Highway Routes to Alaska (1941), 259

Atomic Bombs/Nuclear Weapons, 260

Avenger Field, 261

Primary Document: Letters of Mary Anna Martin Wyall, a Pilot Trainee at Avenger Airfield (1944), 262

B-17 Flying Fortress, 263

Big Science, 264

Blood Transfusion, 265

Bradberry, Henrietta (1903–1979), 266

Calutron Girls, 267

Clarke, Edith (1883–1959), 268

Curtiss-Wright Aeronautical Engineering Cadettes, 269

D Rations, 270

Electric Guitar, 270

Fermi, Enrico (1901–1954), 271

FM Radio, 272

Freeze-Dried Food, 273

Garbage Disposal, 273

Gas Mask, 274

Golden Gate Bridge, 274

Primary Document: Letter of Charles Ellis to the *San Francisco Chronicle* Regarding the Golden Gate Bridge (1930), 275

Helicopter, 276

Hoover Dam, 277

Primary Document: President Franklin D. Roosevelt’s Speech at the Dedication of Hoover Dam (1935), 280

Hydrogen Bomb, 283

Hydroponics, 284

International Ladies’ Garment Workers’ Union (ILGWU), 285

Primary Document: “The Uprising of the 20,000,” 286

Interstate Highway System, 287

Primary Document: Excerpt from the Federal-Aid Highway Act (1956), 289

Lamarr, Hedy (1914–2000), 290

Primary Document: Patent for Hedy Lamarr’s Frequency-Hopping System (1942), 292

Lange, Dorothea (1895–1965), 292

Lend-Lease Program (1941–1945), 293

Liberty Ships, 294

M&M’s, 295

M4 Sherman Tank, 295

Manhattan Project, 296

Mead, Margaret (1901–1978), 297

Microwave Oven, 299

Military Technology (World War II), 299

MIT Radiation Laboratory, 301

Neoprene, 302

Oppenheimer, J. Robert (1904–1967), 303

Paul, Les (1915–2009), 304

Penicillin, 306

pH Meter, 307

Photocopier, 307

Pinball and Arcade Games, 308

Plastic Wrap, 309

Radar, 309

Refrigerator, 310

Richter Scale, 311

Rocketry (Pre–Space Age), 311

Rosie the Riveter, 313

Primary Document: Excerpt from Interview with Maria Isabel Solis (2003), 315
 Schwinger, Julian (1918–1994), 316
 Semple, Ellen Churchill (1863–1932), 317
 SONAR, 318
 Submarine Technology, 319
 Tampon, 320
 Tea Bag, 321
 Telephone, 322

Television, 325
 Tennessee Valley Authority Electricity Project (TVA), 328
 Thomas, Vivien Theodore (1910–1985), 329
 Tizard Mission, 331
 Women's Airforce Service Pilots (WASPs), 331
 Wu, Chien-Shiung (1912–1997), 333

Bibliography: Reconstruction through World War II, 335
Index, 339

VOLUME 3: THE COLD WAR TO THE PRESENT

Section 1: The Cold War (1946–1979), 1

Overview, 1
 911 Emergency System, 8
 Agent Orange, 9
 “Air” Athletic Shoes, 11
 Antiballistic Missiles (ABMs), 11
 Antibiotic, 13
 Apollo Project, 14
 ARPANET, 16
 Aspartame, 18
 Association for Women in Mathematics (AWM), 19
 Atari, 20
 Automotive Technologies (Post–World War II), 22
 Baer, Ralph (1922–2014), 24
 Primary Document: Excerpt from Ralph Baer's Four-Page Paper Describing His Plans for Simple Video Games (1966), 25
 Bar Code Scanner, 25
 Benerito, Ruth Rogan (1916–2013), 27
 Biodiesel, 27
 Primary Document: Statement of Anne Steckel, the Vice President of Federal Affairs of the National Biodiesel Board, to the Senate Committee on Environment and Public Works (2016), 29

Birth Control Pill, 31
 Bomb Disposal Robots/Units, 33
 Brill, Yvonne Madalaine Claeys (1924–2013), 34
 Primary Document: Yvonne Brill's Patent for New Jet Propulsion Technology (1974), 35
 Brown, Marie Van Brittan (1922–1999), 35
 Bulletproof Vest/Kevlar, 36
 Carson, Rachel (1907–1964), 36

1. The Cold War (1946–1979)

OVERVIEW

The years following the end of World War II through 1979 were a time of rapid technological change and scientific discovery in the United States. Many of the innovations of this period had their roots in the World War II war effort, with rapid advancements made in the 30 years afterward.

The end of the war signaled a decline of the old great powers of Europe and the rise of two superpowers: the United States and the Soviet Union (USSR). The political conflict between these two powers (known as the Cold War) resulted in competition that began not only the nuclear arms race but also the Space Race, the exploration of the oceans and the deep interior of Earth, the rise of telecommunications and civilian nuclear power, and greater awareness of the effects that human activities have on the natural world. Scientific and technological developments in a range of fields—agriculture, biomedicine, computer science, ecology, and meteorology, to name just a few—were also directly and indirectly tied to the global conflict and competition that the Cold War entailed.

There is little doubt that science as we know it today was born during this period and that the Cold War expansion of science and technology continues to reverberate throughout contemporary life. What follows is a brief overview of some of the most significant discoveries and advancements of this period and the ways they have changed our world.

The Dawn of Computer Science

The first general-purpose electronic digital computer, the Electronic Numerical Integrator and Computer

(ENIAC), was developed at the University of Pennsylvania during the World War II years to calculate artillery firing tables for the U.S. Army. Its first six programmers—Jean Jennings Bartik, Frances Snyder Holberton, Kathleen McNulty Mauchly Antonelli, Marlyn Wescoff Meltzer, Ruth Lichterman Teitelbaum, and Frances Bilas Spence—were all women mathematics majors specifically recruited for the task. A huge machine weighing 30 tons, ENIAC is believed to have performed more calculations over the 10 years it was in operation than all of humanity had performed until that time.

The development of ENIAC would lead to the UNIVAC I, produced in 1951 by Remington Rand, an early business machines manufacturer. While the military remained a major customer for these \$1 million machines, UNIVAC computers found a place at utilities, insurance companies, and other civilian enterprises. In 1952, mathematician Grace Hopper developed A-0, a program that allowed a computer user to use English-like words instead of numbers to give the UNIVAC instructions, making it even more suitable for business use and forming the basis for future programming languages.

In 1947, physicists John Bardeen and Walter Brattain, working at Bell Telephone Laboratories with supervisor William Shockley, developed the transistor, a much smaller and more reliable means of regulating and transferring electronic signals than the large and fragile glass vacuum tubes that were in use at the time. This invention not only won them the 1956 Nobel Prize for Physics, it revolutionized the electronics industry, making possible not only smaller computers but an entire array of compact devices for both civilian and military use. Transistor radios were one very popular early application in the 1960s and 1970s—those

heavy radio devices that used to sit in large cabinets in living rooms around the country could now be carried in one hand.

In 1961, the Minuteman I, the second generation of intercontinental ballistic missiles (ICBMs) produced by the United States and developed for the purpose of striking cities in the USSR from U.S. soil, used transistorized computers to continuously calculate their position in flight. The military's high standards for its transistors pushed manufacturers to improve quality control, which in turn benefited civilian applications. When Minuteman I units were decommissioned, some universities received these sturdy computers for use by students, recycling military might into tools for the advancement of civilian goals.

Global Communications—The Development of Satellites and the Birth of the Internet

The technological discoveries made in service of the creation of long-range nuclear missiles were also used toward the development and refinement of satellites. Both the United States and USSR were working on satellite programs in the mid-1950s as members of the International Council of Scientific Unions (an organization that promoted scientific cooperation between nations). Yet the U.S. public was shocked by the news of the successful launch of the first satellite, Sputnik I, by the USSR in October 1957. While the purpose of Sputnik was purely scientific—to collect data on the earth's atmosphere—people feared that if the United States were to fall behind the USSR in any capacity, it would put the country at a dangerous political and military disadvantage. This event helped jar the United States into concentrating a great deal of money and expertise on the exploration of space in the coming years.

The value of satellites as commercial communication tools became a subject of great interest to private companies during this period. In 1960, telecommunications company AT&T filed with the Federal Communications Commission (FCC) for permission to launch an experimental communications satellite, with the intention of launching operational ones as soon as possible afterward. The U.S. government was so focused on its competition with the USSR and the military uses of satellites that this event took it by

surprise, but by mid-1961, AT&T was building its own satellite, and the National Aeronautics and Space Administration (NASA) had awarded contracts to electronics manufacturer RCA and Hughes Aircraft Company for two other projects. To regulate these satellites, Congress passed the Communications Satellite Act of 1962, which created the COMSAT Corporation, a publicly funded organization that develops commercial and international satellite communications systems. By 1964, there had been two satellites each from AT&T, RCA, and Hughes put successfully in orbit. Telephone calls and television signals were transmitted via these satellite links, including some of the 1964 Tokyo Olympics. Use of communications satellites grew exponentially in the following years.

Encouraged by the successes of the U.S. military and commercial satellite programs, other government agencies took an interest in satellites for civilian purposes. In September 1966, the U.S. Department of the Interior, NASA, and the U.S. Department of Agriculture embarked on a project to develop an observation satellite to take specialized photographs of the earth, enabling people to study and evaluate the changes caused by both natural processes and human practices. This goal was achieved in July 1972 with the launch of the Earth Resources Technology Satellite (ERTS-1), later renamed Landsat 1. Landsat satellites have been in orbit ever since, continually adding to the digital archive.

The Defense Advanced Research Projects Agency (DARPA) was another government organization created as a result of the shock of Sputnik. Initiated in February 1958, DARPA would also work on satellite technologies for the purposes of reconnaissance and recording weather observations. However, its best-known and farthest-reaching project would start with the use of dedicated land-based telephone lines.

DARPA research played a central role in launching what is now known as the information age, including developing or furthering much of the basis for the Advanced Research Projects Agency Network (ARPANET), a pioneering network for sharing digital resources among geographically separated computers. Its initial demonstration in 1969 led to the Internet, with world-changing consequences that continue to unfold today.

As ARPANET was being developed, DARPA and the U.S. Air Force also funded a groundbreaking computer framework known as the oN-Line System (NLS). Conceived by engineer and inventor Douglas Engelbart and developed with colleagues at the Stanford Research Institute (SRI), the NLS system was the first to feature hypertext links, a mouse, video monitors, information organized by relevance, on-screen windows, presentation programs, and other modern computing concepts. In what became known as “the Mother of All Demos” because it demonstrated such a wide array of revolutionary features, Engelbart unveiled his system in December 1968 to the audience at the Fall Joint Computer Conference in San Francisco, California. Engelbart’s terminal was linked to a large-format video projection system and via telephone lines to a computer 30 miles away in Menlo Park, California, at SRI’s Augmentation Research Center. The audience could see Engelbart manipulate the mouse and watch as members of his team in Menlo Park joined in the presentation. NLS opened pathways toward today’s wide array of information technologies. The NLS was one of the first to be connected to the ARPANET when it debuted in 1969, along with computing research centers at the University of California, Los Angeles; the University of California, Santa Barbara; and the University of Utah School of Computing.

Another seminal moment in the emergence of today’s Internet occurred in 1973, when electrical engineer Robert Kahn at DARPA asked computer scientist Vinton Cerf, then working at Stanford University, to collaborate on a project to develop an efficient, reliable, and robust method of sending data across the ARPANET. Their work resulted in the creation of the Transmission Control Protocol (TCP) and the Internet Protocol (IP), most often seen together as TCP/IP. These protocols remain a mainstay of the Internet’s unseen technical foundation even today. Kahn and Cerf are referred to as the “Fathers of the Internet” for their invention.

The ARPANET continued to expand, growing from 4 nodes to 38 by 1973, each connecting a university or defense-related data center to the network. The operators of ARPANET realized the system they had built could be of great value for commercial and public use, but the businesses of that day with the infrastructure and deep pockets to build such a network

(mainly AT&T and Western Union) were reluctant to take on the task. A group of developers and engineers who had worked for DARPA and associated private firms thus formed their own company, Telenet, which the FCC approved to sell network communication services in 1974, marking the birth of the first Internet Service Provider (ISP). In its FCC application, Telenet proposed building a hybrid system of terrestrial cabling and satellite links. It started offering services in seven cities in August 1975. This jumped rapidly to 16 cities by the end of 1975, 47 by the end of 1976, and 81 by the end of 1977.

The Space Race

By the mid-1950s, the Cold War had become the background upon which everyday life played out in both the United States and the USSR. The Korean War, the growing numbers and power of nuclear weapons, and the differences in political thought and opinion between the two countries had led to a growing feeling of unease. The shock of the USSR launching Sputnik I in 1957 had jarred the United States to its core. Space was considered the next new frontier in the American tradition of exploration, which the Soviets were now impinging upon. Additionally, the missile used to launch Sputnik into space—the R-7 ICBM—seemed capable of delivering a nuclear warhead to U.S. soil, making gathering intelligence about Soviet military activities especially urgent.

The launch of Sputnik I signaled the start of the Space Race. The USSR followed Sputnik I with Sputnik II in November 1957, and then in January 1958, the United States launched its first satellite, Explorer-I. The States then created the National Aeronautics and Space Administration (NASA) in October 1958, a new organization dedicated to the exploration of space.

At the same time, President Dwight D. Eisenhower also created two additional space programs with national security as their primary goal. The U.S. Air Force directed one program that explored the military potential of space. The other, led by the Central Intelligence Agency (CIA), the Air Force, and a new organization called the National Reconnaissance Office, used orbiting satellites to gather intelligence on the Soviet Union and its allies. This program was

code-named Corona; the existence of the National Reconnaissance Office would be kept secret until the mid-1990s.

The next goal would be to launch a human into space; the Soviet cosmonaut Yuri Gagarin was the first person to go into space in April 1961. The following month, U.S. astronaut Alan Shepard became the first American in space. Shortly thereafter, President John F. Kennedy pronounced that the United States would land a man on the moon before the end of the decade. This pledge was fulfilled on July 20, 1969, when U.S. astronaut Neil Armstrong, as part of the Apollo 11 crew, became the first man to walk on the moon's surface. People at home, thanks to the relatively new medium of television, followed along intently in what might be considered the biggest television event of the 20th century. Broadcasting the moon landing was made possible by a special low-light camera developed by Westinghouse, whose original purpose was for jungle surveillance in the Vietnam War; Intelsat satellites and AT&T landlines would be part of the communications links that would broadcast the signal to the world.

By landing on the moon, the United States effectively “won” the Space Race—the Soviets never succeeded in making a moon landing, and interest in lunar landings began to wane after the early 1970s. Additionally, both countries began to see benefit in working cooperatively rather than competitively on space missions; in July 1975, the joint Apollo-Soyuz mission sent three U.S. astronauts in an Apollo spacecraft to dock with two cosmonauts in a Soviet-made Soyuz vehicle. When the commanders officially greeted each other, their handshake in space served to symbolize an improvement in relations between the two countries.

Advances in Biological Science and Medicine

While researchers in the computer science and communications fields were expanding the ability and ease of communicating nationally and globally, another set of scientists were looking inward, deep into the inner workings of not only the human body, but of all life on earth.

Scientists had known about the existence of animal and human cells since the invention of the microscope in the mid-1600s and had theorized about their

structure, purposes, and behavior since the late 1830s, but success in growing strains of specific cells—an important step in the development of safe and effective vaccines as well as certain cancer treatments, and in genetic research—did not find reliable success until the mid-1940s. Prior to this time, there were not many vaccines in existence, and they often relied on either live animals or animal tissue cultures for their raw materials. This made the study of viruses and the development of vaccines against them slow and difficult. Virologist John Enders and his team at Boston's Children's Hospital developed cell culture techniques that allowed scientists to grow large supplies of many viruses in a wide variety of cell types.

This quickly led to vaccines being developed for polio, measles, and mumps. At the time Enders and his team started their work in 1945, only 13 human viral pathogens had been isolated. By 1961, 58 more had been cultured, along with another 300 viruses that infect animals. Millions of people and animals have benefited from the vaccines developed as a result. Enders and colleagues Thomas H. Weller and Frederick C. Robbins were awarded the Nobel Prize in Physiology or Medicine in 1954 for their work. Other scientists would take an even deeper dive, looking for and trying to understand the most basic building blocks of the cell. The era of modern biology would be born with those discoveries.

Back in 1868, a young Swiss physician named Friedrich Miescher was the first person to isolate genetic material from a cell. He called the compound he discovered “nuclein,” now called nucleic acid. This is the “NA” in DNA (deoxyribonucleic acid) and RNA (ribonucleic acid). It would take until 1944 for scientists to understand the connection between nucleic acid and genes, when the American scientist Oswald Avery managed to transfer the ability to cause disease from one strain of bacteria to another. He also found that the previously harmless bacteria could also pass their new disease-causing trait along. What Avery had moved was nucleic acid, and his experiment showed that genes are made of it.

These discoveries set the stage for one of the most significant biological discoveries ever made: in April 1953, the structure of DNA was revealed. DNA is a code, a means of storing biological data in the form of

genes, which are made of chemicals called “amino acids.” The same set of amino acids are encoded by DNA in all life-forms, whether they be single-celled bacteria, plants, animals, or human beings. Figuring out DNA’s structure has allowed it to be studied and manipulated, greatly furthering our understanding of genes and their role in some forms of disease.

In 1962, molecular biologists Francis Crick, James Watson, and Maurice Wilkins shared the Nobel Prize in Physiology or Medicine for this discovery. This advance was also responsible for the birth of biotechnology, a new field in biology. In California in the early 1970s, scientists invented ways to swap bits of DNA from one organism to another. Since all life is made from the same building blocks, it is possible to do this even between different species. These techniques are being used to research cures for genetic diseases and cancer.

The development of life-saving drugs also saw a golden age in the Cold War era. The first true antibiotic, penicillin, was discovered by accident in 1928 by British bacteriologist Alexander Fleming. He noticed that some bacteria he was trying to grow in glass dishes had been contaminated by a mold—penicillin—and that it was killing that bacteria. Ten years would go by, however, until other scientists tried to purify and grow penicillin for the purposes of testing it for possible use as a medicine. The war effort underway in Britain at that time severely curtailed that country’s ability to do both the large-scale growing of the penicillin mold and the testing required to make sure it was safe, so scientists traveled to the United States to ask for help. The Department of Agriculture’s Northern Regional Research Laboratory (NRRL) in Peoria, Illinois, took on the project in 1941. Other government agencies and pharmaceutical companies soon signed on to help once it was realized how valuable a drug like this could be, especially in wartime, when so many wounded soldiers died of bacterial infections. One of the major goals was to have an adequate supply of the drug on hand to treat casualties from the D-Day invasion of Europe on June 6, 1944.

By 1949, the annual production of penicillin in the United States was in the billions of units, and the price had dropped dramatically, making a life-saving medicine both very inexpensive and widely available. The race was then on to discover additional substances that

would have the same effects on a wider range of bacterial illnesses. The 1950s through the 1970s are considered a golden age of antibiotic discovery, with eight additional classes of antibiotics being introduced. Drugs such as streptomycin, tetracycline, chloramphenicol, erythromycin, rifampicin, and vancomycin were added to the antibiotic arsenal during this time. Chloramphenicol would be the first antibiotic to be created entirely in the laboratory during this period, making it very easy and inexpensive to produce.

The discovery and development of antibiotics has been recognized as one of the greatest advances in therapeutic medicine. Additionally, it was also found that some naturally occurring substances could be used against fungal diseases. Microbiologist Elizabeth Lee Hazen and chemist Rachel Fuller Brown at the Division of Laboratories and Research of the New York State Department of Health would discover nystatin, which was effective against fungal infections of the skin, mouth, throat, and intestinal tract. It was introduced for commercial use in 1954.

Nuclear Arms and Development of Civilian Nuclear Power

Scientists first began teasing out the structure of atoms and their properties in the early 1900s. Coupling this with research on radioactive elements, by the late 1930s, scientists discovered that energy—a lot of it—could be produced by splitting atoms. At that time, British and American physicists looking at this discovery saw different uses for the knowledge. Britain, already embroiled in World War II, saw the potential for a bomb first (and worried that the Germans might already be developing such a weapon), while the United States was initially more interested in developing nuclear energy to run power plants and ships. The U.S. entry into World War II in late 1941 changed this priority drastically, with the ultimate result, the United States developing and dropping two nuclear bombs on Japanese cities, ending the war.

The demonstration of the awesome power of these weapons and their implications was not lost on the rest of the world, especially the United States’ biggest rival. The USSR stepped up its efforts to build such a weapon of its own, testing its first one in 1949. This

would lead to other countries developing and testing nuclear weapons throughout the 1950s, and also to much larger, more powerful bombs.

Tensions came to a head in November 1962 when the United States discovered that the USSR had nuclear missile installations in Cuba, only 90 miles from the Florida coast. This very nearly provoked a nuclear war, and although the Soviet Union backed down at the last moment, both sides had been deeply shaken by the standoff.

This event, along with escalating concerns and protests regarding the effects of nuclear testing on human health and the environment, led to an agreement between the United States, the USSR, and Britain to ban nuclear testing in the atmosphere in August 1963. Five years later, the Nuclear Non-Proliferation Treaty was signed, with non-nuclear-weapon countries agreeing never to acquire nuclear weapons, and the nuclear-weapon states agreeing to pursue nuclear disarmament.

Even in the midst of the turmoil over nuclear arms, nuclear technology started to find uses in peacetime applications, mainly in the production of steam power and electricity. The first nuclear reactor to produce electricity came online in 1951. Named the Experimental Breeder Reactor, it was designed and operated by Argonne National Laboratory in Idaho. Two years later, President Eisenhower proposed an “Atoms for Peace” program, which directed the country’s considerable nuclear research efforts toward electricity generation and set the course for nuclear energy development in the United States. Part of the Nuclear Non-Proliferation Treaty agreement stipulated that nuclear-weapon states share their knowledge of peaceful use of such energy with all other signatories to the agreement.

Even peaceful use of such energy was not always met with acceptance, however. Protestors would find success in limiting the growth of nuclear energy, starting with a demonstration in April 1977 at the construction site for what would become the Seabrook (New Hampshire) Nuclear Power Plant. Resulting in one of the largest mass arrests in U.S. history, the Seabrook action initiated a backlash against nuclear power that played a significant role in limiting the construction of reactors across the country. Dangerous accidents, such

as the partial meltdown of the nuclear core at the Three Mile Island reactor in Pennsylvania in March 1979, helped cement resistance to reactor construction.

The Rise of Environmental Activism

Along with the advancement of science and technology also came concern, first from scientists and then the general public, of how those advances affected the natural world around us and how some of it might have detrimental and even catastrophic effects. The worry that revolved around the destructive power of nuclear weapons and toxic effects of radioactive waste from power plants widened to encompass other areas.

One key figure in examining the negative effects of advancements during this period was Rachel Carson, a marine biologist who joined the U.S. Bureau of Fisheries (which later became part of the U.S. Fish and Wildlife Service) in 1935. Her second book about life in the ocean, *The Sea Around Us*, benefited from research that came as a result of data obtained from submarine warfare of World War II. A gifted writer and storyteller, she was able to package this information into an engaging general-interest book that explained the science of the sea. Published in 1951, it became a best seller, won the National Book Award for nonfiction that following year, and enabled her to quit her job and write full time.

Carson then turned her attention to a problem that had concerned her for at least a decade: the widespread and indiscriminate use of chemicals in agriculture and pest control, most notably DDT. A powerful and long-lasting insecticide discovered by Swiss chemist Paul Hermann Muller at the outbreak of World War II (he would win a Nobel Prize in Physiology and Medicine in 1948 for the discovery), DDT was initially used during the second half of World War II to kill the insects that transmitted malaria and typhus to both civilians and troops. DDT then made a jump to commercial use on crops and home gardens.

Carson’s next book, *Silent Spring*, published in 1962, warned of the dangers to all natural systems from the indiscriminate use of such pesticides and questioned the scope and direction of modern science. *Silent Spring* helped transform and broaden the conservation movement of the previous era into a more

comprehensive and informed environmentalism, and is partially credited for the formation of the U.S. Environmental Protection Agency at the end of 1970.

The new environmental activists would be responsible for actions such as protests against the use of Agent Orange during the Vietnam War. Agent Orange was a mix of vegetation-killing chemicals that was sprayed (along with other herbicides) by the millions of gallons onto Vietnamese forests, jungles, and food crops by the U.S. military between 1962 and 1971. The purpose of the spraying was to deny guerrillas places to hide and to reduce the enemy's food supply. It was found to contain the highly toxic chemical dioxin and is believed to have caused cancer, neurological illnesses, and other serious ailments in both American and Vietnamese soldiers and civilians who were exposed to it, along with birth defects in children. Gaining critical momentum 1968 and often occurring hand in hand with protests against the increasingly unpopular war, the spraying of Agent Orange was suspended in 1970, and all spraying stopped the following year.

The Development and Widespread Use of Synthetic Materials

Another technological advance with wide-ranging effects was the rapid expansion of the development and use of synthetic materials. The invention of plastics was born out of the need to produce items that did not involve the use of natural materials such as wood, metal, or stone. Especially during World War II, these materials were scarce, and replacements that were strong, lightweight, and inexpensive to manufacture were of critical importance. Plastics provided those substitutes. Nylon, invented by DuPont organic chemist Wallace Carothers in 1935 as an alternative to silk, was used for items such as parachutes and ropes. Plexiglas was an excellent alternative to glass for aircraft windows. During World War II, plastic production in the United States soared and continued to rise afterward as the economy expanded and demand for consumer goods came with it. Plastics made possible the development of items such as transistors, critical to the development of computers and a wide range of small electronics, during the early Cold War years of the late 1940s and early 1950s.

Plastics are used in almost all items produced today, including cars and trucks, aircraft, household goods, medical equipment, and clothing.

Synthetic rubber made its appearance during the World War II years when the supply of natural rubber from Asia was cut off. Teams of researchers in government, academic, and industrial laboratories moved from development to manufacture of synthetic rubber in the astounding span of only 18 months—a remarkable scientific and engineering achievement. As with plastic, its production continued to rise as the consumer culture took hold.

Today 70 percent of the rubber used in manufacturing is synthetic and is a descendant of this original, general-purpose rubber substitute. Items such as car and truck tires are frequently made with combinations of synthetic rubber and plastics such as nylon. Items of convenience made with plastic began appearing in the late 1940s and early 1950s as well, with the introduction of food containers such as Tupperware and the disposable diaper.

But the negative aspects of plastic use also became evident. That plastic-lined diaper might have been convenient, but once thrown away, it didn't go away, because most plastics don't decompose. Plastic debris in the oceans was first observed in the 1960s, heightening concerns about its effects on the environment. The first recycling mill to accept residential plastics opened in Conshohocken, Pennsylvania, in 1972 in early recognition of this problem. Most plastics are also derived from oil and gas, which is itself a finite resource, and a problem that modern science and technology is just beginning to address.

The next era in advancements would build on the remarkable achievements of this period and refine and add to them, as well as find new ways to deal with unforeseen problems.

911 Emergency System

The three digit telephone number 911 was the emergency number designated by the United States in 1968. It provides the public with quick and easy access to a public safety answering point (PSAP). Over 95 percent of the United States has access to the Enhanced 911 system (E911), which automatically provides an emergency responder with the caller’s closest address. This number is intended for emergency use only, and attempting to use it for any other purpose, such as a prank call, is considered a crime.

Before the invention of the rotary dial telephone, which gave callers the ability to manually dial a phone number, the use of an operator was required to make a call. In an emergency situation, the caller would have to wait for an operator to pick up and describe the dilemma, and the operator then had to connect the call manually via switchboard. The United Kingdom pioneered the idea of a national emergency number in 1937 using the number 999.

In the United States, the idea for the 911 service originated from the National Association of Fire Chiefs in 1957, when it recommended a single service number for reporting fire-related emergencies. In 1967, the President’s Commission on Law Enforcement and Administration of Justice recommended a single contact for emergency situations be used nationwide. In 1967, the Federal Communications Commission met with American Telephone and Telegraph Company (AT&T) to choose a number, and 911 became the national emergency number in 1968. It

was chosen because it was easy to remember and dial, and it worked well with current phone systems. Although 911 was the national number for emergencies, it did not become widely recognized or available until as late as the 1980s. Canada also uses a 911 system, as do many Caribbean nations.

The system used today is significantly more sophisticated than the original system. Enhanced 911 (E911) provides the emergency dispatcher with the caller's location and is available in over 95 percent of the United States. Using the database function called automatic location identification (ALI), emergency operators can obtain a caller's telephone number and location. The information is gathered by mapping the caller's phone number to a nearby address database. Mobile phones can also provide an emergency operator with location information. This is obtained through radiolocation through a cell tower or through a Global Positioning System within the caller's mobile phone.

The funding for 911 comes from local households and businesses. This appears as a nominal fee on the caller's phone bill, and there is no per-call charge for 911. The caller may be charged for ambulances dispatched through 911 or Enhanced 911; however, this is not a 911 expense but a separate bill.

Agent Orange

Agent Orange is a blend of herbicides and defoliants sprayed by U.S. military forces in the Korean and Vietnamese conflicts. Questions about the long-term health effects caused by exposure to the agent, including an increased risk of cancer, ended its legal use.

The first use of tactical herbicides in warfare began in the early 1950s, when British forces employed

massive amounts of defoliants to destroy the insurgents' food crops during the Malayan Emergency. In 1961, the South Vietnamese president Ngo Dinh Diem asked the White House to start an aerial herbicide campaign in his country in an effort to deprive Vietcong fighters of their cover. In November of that year, President John F. Kennedy authorized the start of Operation Ranch Hand, an herbicidal warfare program during which the rural areas of South Vietnam, Laos, and Cambodia were sprayed with 20 million U.S. gallons (76,000 m³) of Agent Orange. The U.S. Air Force used specially refitted Fairchild C-123 Providers that used the call sign "Hades." The herbicide was also used to defoliate the perimeters of military bases and in ships and boats that operated until at least May 1975.

Named by the orange-striped, 55-gallon drums in which it was originally shipped, Agent Orange was manufactured by nine wartime government contractors, although the vast majority of it was produced by the former Monsanto Company and Dow Chemical. It was a combination of equal amounts of two active ingredients: 2,4-dichlorophenoxyacetic acid (2,4-D) and 2,4,5-trichlorophenoxyacetic acid (2,4,5-T). The latter one contained traces of 2,3,7,8-tetrachlorodibenzo-p-dioxin (TCDD) as an unwanted byproduct of the chemical reactions.

Hundreds of thousands of U.S. soldiers and nearly 4 million Vietnamese citizens were exposed to Agent Orange during the Vietnam War and in subsequent operations. In 1994, several aircraft used during the Vietnam War were still heavily contaminated. The chemical substance was sprayed from boats, trucks, airplanes, helicopters, and even on foot by soldiers with backpack sprayers. Exposure occurred by breathing the chemical, ingesting food or drink that were contaminated by it, or even by skin and eye contact.

Numerous studies have evaluated the toxicity and the detrimental health effects linked to Agent Orange and its dioxin byproducts. 2,3,7,8-TCDD is, in fact, the most dangerous of all polychlorinated dibenzodioxins (PCDDs or dioxins) and can be highly toxic and teratogenic even in minute doses. TCDD has been classified as a known human carcinogen by several national and international agencies, including the International Agency for Research on Cancer (IARC), the U.S. Environmental Protection Agency (EPA), and

A C-123 aircraft sprays the chemical herbicide and defoliant Agent Orange across a field near Saigon, Vietnam, in 1970. During the Vietnam War, the U.S. Air Force sprayed Agent Orange to clear jungles that provided enemy cover. (Dick Swanson/The LIFE Images Collection/Getty Images)

the U.S. National Toxicology Program (NTP). Agent Orange was sprayed on 3.1 million hectares (12,000 square miles) of jungle, nearly 20 percent of the total forested area of Vietnam, exerting a heavy toll on the local ecological balance. Persistent dioxin contamination settled in the soil and water and entered the food chain, and terrain erosion caused by the loss of trees negatively impacted local ecosystems. Agent Orange was also used or tested by other governments, such as the Republic of Korea in 1960 and the Philippines in 1969.

In 1972, the U.S. Air Force started an operation to remove all remaining Agent Orange barrels from Vietnam, called Operation Pacer IVY. A total of that 1.8 million gallons of the herbicide were collected and stocked on Johnston Atoll, while another 480,000

gallons were stored at Gulfport, Mississippi. From July to September 1977, the herbicides were safely disposed of through incineration in special conditions on board the Dutch ship MT *Vulcanus* during Operation Pacer HO.

“Air” Athletic Shoes

Invented by a NASA aeronautical engineer, Marion Frank Rudy, “air” athletic shoes were designed using the same technology that made helmets for astronauts. Rudy patented his cushioning system in 1979 that is based on inert gas encapsulated in polyurethane plastics. His work was then trademarked by Nike as the “air” sole. This is one of the many examples of spin-offs of NASA technologies and their impact on society.

NASA spin-offs are “invented to describe specific technologies developed by NASA for its missions that are transferred for commercial use or some other beneficial application.” In the 1970s, NASA and Nike crossed paths. Almost all inventions at the time seemed to trace back to the Apollo missions. The Nike Air Tailwind was released in 1978 with the new rubber-molding technology. The technology allowed Rudy to design a hollowed-out midsole in which he imbedded polyurethane pouches filled with dense gases.

The company marketed the shoes on the assumption that “running on air” would provide the best support and cushioning. The other added benefit was the sacs of gas within the design, which would not wear out even after repeated use. Due to these assumptions, Nike Air was marketed only to elite runners. In the 1980s, Nike discovered that consumers would pay \$100 or more for a pair of “air” athletic shoes.

Nike continued to develop the air shoe technology, which became a defining brand for it, especially when it came to establishing superiority in technology-driven design. Nike became a billion-dollar company in 1986 when it also released its new design of air shoes called the Air Max. This design involved a window in the sole of the shoe that made the air visible to consumers. Besides simply seeing the air, consumers could also poke the gas packet and feel the bounce.

This technology and design evoked excitement among shoe buyers in the 1980s and 1990s because sneakers had become personal gadgets that made consumers feel more like professional athletes. Nike also stressed technology that made the sneakers look futuristic. The Nike Air design was revamped many times with various configurations and locations of the

visible air. However, in the 1990s, studies found that athletes performed better when they trained barefoot. This completely changed Nike’s strategy to investment in a super-flexible shoe with minimal cushioning and maximum flexibility.

Research has also shown that too little cushioning can also be harmful, creating a backlash against the barefoot running fad. Some athletes are moving back to traditional cushioned shoes.

Regardless of shoe preference, few consumers know that the most popular sneaker trend of the late 20th century was based on NASA technology. Other NASA spin-offs include improved infant formula, virtual reality technology, memory foam, satellite television, invisible braces, scratch-proof eyeglass lenses, home water-filtration systems, and cordless tools.

Antiballistic Missiles (ABMs)

A ballistic missile is a missile that is powered and aimed to hit a specific target. Antiballistic missiles (ABM) are a military defense strategy using air missiles to counterattack ballistic missiles while they are still in flight. The ABM knows where to hit the missile by intercepting its target based on its ballistic trajectory—where the missile will go down due to gravity. Ballistic missiles can carry nuclear, chemical, or biological substances, making ABMs an important defense strategy. Though there are many different types of missiles, the antiballistic missile was and still is specifically airborne.

In the 1940s, United States, Germany, and the Soviet Union were working on ABM technology. German V-1 and V-2 programs worked to develop “flying bombs,” some of which were intended to destroy

incoming missiles. At the same time, in the United States, Bell Labs determined that the technology needed to hit a flying missile did not exist.

At the end of World War II in 1945, the U.S. Department of Defense began significant research into ABMs. Improved computing systems in the 1950s made ABMs seem more possible. Early ABM systems proved so expensive that the American defense department determined that it would be cheaper and just as effective to build more nuclear weapons, thus preventing a Soviet nuclear strike through the principle of “mutually assured destruction.” In 1957, the LIM-49 Nike Zeus first went into development. The Zeus became designated a national priority in 1958. In 1962, Zeus testing proved that the ABM could successfully hit targets. Nonetheless, the Zeus was never mass-produced, in part because the proliferation of intercontinental ballistic missiles (ICBMs) made intercepting all of them an impossibility.

The answer to that problem came with the Anti-Ballistic Missile Treaty of 1972, which limited how many missiles the United States and the Soviet Union could build. The treaty also prohibited and permitted what both of the countries were able to do and not do, ranging from developing, testing, and deploying, to both countries having to make amendments, as well as addressing any issues that might oppose compliance to the treaty. Additionally, with the treaty, the two nations were obligated not to deploy ABM missiles, and both parties had to discuss any new invention that replaced anything related to antiballistic missiles. Another name for the Anti-Ballistic Missile Treaty of 1972 was the Strategic Arms Limitation Talks (SALT) Treaty. In May 1972, U.S. president Richard Nixon and Soviet general Leonid Brezhnev had signed the agreement to limit the number of nuclear missiles in both countries’ arsenals.

In 1974, President Richard Nixon inaugurated the Strategic Defense Initiative (SDI), famously known as “Star Wars.” The Strategic Defense Initiative conducted research and experiments to find ways to intercept the intercontinental ballistic missiles (ICBMs) and submarine-launched ballistic missiles (SLBMs) as well. The Star Wars program was immensely controversial because parts of it were secret; it threatened to destabilize the SALT Treaty and threatened to

restart the arms race. As a result, the budget for the program was significantly decreased until President George W. Bush attempted to revive it.

In the 1980s, the Brilliant Pebbles became the centerpiece of the Bush administration’s Strategic Defense Initiative. Satellite-based nonnuclear tungsten projectiles, working in concert with the Brilliant Eyes sensing system, were meant to act as a space-centered ABM system. The Defense Department spent millions on the program and then canceled it in 1994. Nonetheless, the sensor systems developed in the program played an important role in 21st-century missile defense.

The United States withdrew from the Anti-Ballistic Missile Treaty in 2002. Its government argued that missiles from so-called rogue states made ABM technology too important to limit in any way. The day after the United States dropped out of the treaty, Russia dropped out of the Strategic Arms Reduction Treaty.

The Terminal High Altitude Area Defense (THAAD) is a military defense system and uses antiballistic missiles to shoot down any ballistic missile of any range. First funded by the U.S. Army, Lockheed Martin took over the program as the primary contractor in 2008. This defense system was officially deployed in 2012 and is currently installed in the United Arab Emirates, Turkey, and South Korea.

American ABM deployment continues to play an important part in national defense. In 2004, the U.S. Army announced plans to develop ABM systems that would replace seven systems currently in use. New ABM systems aim to shoot down short-, medium-, and intermediate-range missiles. On March 7, 2017, the United States deployed two antiballistic missiles as way to threaten North Korea after it first fired four ballistic missiles into the ocean near Japan.

Antibiotic

In 1950, the biochemist Rachel Fuller Brown and the microbiologist Elizabeth Hazen codiscovered nystatin, the first antibiotic drug that could effectively treat fungal diseases in humans. Brown and Hazen donated all the profits of nystatin, which is still widely used today, to philanthropic and scientific research. The over \$13 million earned with their breakthrough discovery’s royalties helped many other young women to follow in their footsteps.

Elizabeth Lee Hazen was born in Rich, Mississippi, on August 24, 1885. Orphaned at the age of four, she and her two siblings were adopted by their father’s brother. They all lived in poverty, but her zealous devotion to reading and studying allowed her to excel in academic results. In 1905, she enrolled at the Mississippi University for Women, obtaining a bachelor of science degree in 1910. Up until 1916, she taught physics and biology at Central High School in Jackson, Mississippi, while attending summer study at the University of Tennessee and the University of Virginia. Later she moved to New York City to attend Columbia University, where she was one of the first female students to obtain a master’s in biology there, which she did in 1917, and a PhD in microbiology in 1927.

During World War I, she served in the army as a diagnostic laboratory technician at Camp Sheridan, Alabama, and Camp Mills, New York. In 1931, Hazen started working with the New York State Department of Health, where she was put in charge of the Bacterial Diagnosis Laboratory in Albany, New York. While there, she traced an outbreak of lethal anthrax, located sources of tularemia, and reported the first case in the United States of *Clostridium botulinum*, a source of food poisoning from improperly preserved foods. Hazen also studied in Rhoda W. Benham’s

(1895–1957) mycology laboratory, where she learned a lot about fungi and fungal diseases. After discovering that the fungus *Microsporium audouinii* was responsible for hair loss in school-age children, in 1944, she started producing her own culture collection that later became a state-approved laboratory that helped physicians across the country to identify pathogenic fungi. In the same year, Augustus Wadsworth (1872–1954), founder and head of the division, chose her to lead an investigation into the relationship between fungi and other microbes such as bacteria. After penicillin was discovered in 1928, in fact, many patients treated with the new drug subsequently developed fungal infections in the mouth, skin, and feet as a side effect. Since the team aimed at developing a new substance with antifungal properties, an expert biochemist was needed, and Rachel Fuller Brown was chosen.

Rachel Fuller Brown was born on November 23, 1898, in Springfield, Massachusetts, but she moved to Missouri with her family shortly afterward. During her childhood, Brown always tried to avoid science classes but was fascinated with insects, which she began to collect. In 1912, her father, a real estate agent, left the family, leaving them destitute and forcing her, her mother, and her younger brother to move back to Springfield. Once there, Brown attended Central High School, trying to avoid studying chemistry or physics. Although her mother was too poor to pay for a higher-education degree, Brown’s excellent grades and determination impressed Henrietta F. Dexter, a wealthy friend of her grandmother, who decided to pay for Brown’s tuition at Mount Holyoke College, a college for women in South Hadley, Massachusetts. Brown initially chose to major in history, but after taking chemistry as a compulsory science subject, she graduated with a double major in history and chemistry in 1920.

In 1921, she took a master’s degree in organic chemistry at the University of Chicago. After working as a science teacher in a local girls’ school for three more years, in 1924, Brown returned to the University of Chicago to take a PhD in chemistry and bacteriology. Although she completed her doctorate in just two years, an unexplained delay in arranging her oral examinations prevented her from completing her degree. Since she had no money left, Brown had to

leave Chicago to accept work as an assistant chemist in the research department of the New York State Department of Health. Here, Brown focused her studies on identifying the types of bacteria that caused pneumonia, a disease for which she helped develop a vaccine still used today. She completed the last step for her PhD only several years later. After repaying the educational grants from which she had benefited, her new lifelong objective became helping the poorest youths across the country receive a proper education.

In 1948, Hazen and Brown started working on a new antibiotic to fight fungal infections. Hazen gathered many soil samples from all over the country, where she cultured various bacteria with antifungal properties such as *Actinomyces*. Whenever she found a substance that was effective in killing two strains of pathogenic fungi, *Candida albicans* and *Cryptococcus neoformans*, she sent it to Brown, who isolated the active compound and purified it. After many years of testing, Hazen found a promising bacterium in the soil of William Nourse's dairy farm in Virginia. She named it *Streptomyces noursei* and sent it to Brown, who purified an active compound that was effective against several strains of fungi. After testing its safety in animal experiments, in 1950, the two scientists announced their breakthrough discovery of nystatin, a substance named in honor of the New York State Department of Public Health. In 1954, the pharmaceutical company E. R. Squibb bought it and started mass-scale production of the drug.

All nystatin's patent royalties were assigned by Brown and Hazen to the Research Corporation of New York and the Brown-Hazen Fund. From 1957 to 1978, the fund supported training, research, and other programs to encourage women to take up careers in the biomedical sciences. In May 1975, the two women were the first to receive the Chemical Pioneer Award of the American Institute of Chemists. Brown died at the age of 81 on January 14, 1980, in Albany. Hazen died of acute cardiac arrhythmia on June 24, 1975, in a nursing home in Seattle.

Apollo Project

The ultimate mission of the Apollo Project was to land an American on the moon by the end of the 1960s. By the late 1950s, the Soviets had developed superior space technologies. Analysts feared that this Soviet achievement might convince other nations that the Soviet Union was the most advanced and most powerful nation in the world. President John F. Kennedy (1961–1963) sought to counter that by intensifying the U.S.-Soviet space race.

In terms of the percentage of the national budget, the Apollo Project was the largest single scientific program ever undertaken by the United States. Even though some critics raised concerns over the high price tag of the project and safety issues, most Americans supported the idea of outdoing the Soviets through American technological innovation. In spite of the political origins of the Apollo Project, its success made it the highest technological achievement of mankind, which spawned other space ventures including the manned Space Shuttle program and the unmanned Voyager spacecraft.

In 1957, the Soviet Sputnik I satellite was the first man-made object to successfully orbit the earth. To many people, this Soviet achievement signaled Soviet technological superiority. It also implied the superiority of the Soviet Communist system, which had produced it. During the Cold War (1945–1989), a period when the Soviet Union and the United States were competing for world dominance, Soviet space successes might have led to greater world support for the Soviet agenda.

Shortly after taking office in 1961, President Kennedy made the Space Race an American priority. Kennedy believed that the United States had superior economic and technological resources that would allow it to catch up to Soviet achievements and eventually surpass them. Kennedy chose a goal that was not too far in the future that could cause people to lose

interest, but also not too close in the future, which could render it impossible. He stated: “I believe that this nation should commit itself to achieving the goal, before the decade is out, of landing a man on the moon and returning him safely to the Earth.”

According to National Aeronautics and Space Administration (NASA) reports, the cost of the Apollo Project was \$20 billion, which was more than 2 percent of the entire U.S. budget in the 1960s. Critics charged that the money should be spent in other ways, such as to address urgent human problems (including health issues, food shortages, and homelessness). They also questioned the ethics of sending humans on dangerous space missions. Some critics argued that the Apollo Project was a mistake, because unmanned space exploration was much cheaper and safer. However, NASA had more than enough volunteers willing to take the inherent risks, and many Americans supported the project.

The plan was to use a Saturn V rocket to boost the Apollo spacecraft out of the earth’s gravitational pull. Once in space, the rocket would then fire a second time and send the spacecraft darting to the moon. The spacecraft was designed with three major compartments: a command module (which housed the astronauts and navigation instruments), a service module (which carried water, oxygen, and fuel), and a lunar model designed to transport two astronauts to and from the moon’s surface while a third crewman remained in the command module.

The Apollo Project began with a series of tests. After more than 12 unmanned suborbital and orbital flights between 1961 and 1966, the project team decided that the craft was ready for a human crew. Apollo 1 was a disaster. On January 27, 1967, the craft exploded, and the three crew members died in the fire. NASA scientists suspended the Apollo Project for more than a year to redesign the craft in an effort to increase crew safety. NASA then conducted tests with the next five unmanned missions, Apollo 2 through Apollo 6. Apollo 7, the first manned mission since the Apollo 1 tragedy, was launched on October 11, 1968. For 10 days and 20 hours, the crew orbited the earth and then returned safely. Launched on December 21, 1968, Apollo 8 orbited the moon during Christmas day and then returned safely to earth. Both Apollo 9 (March 3, 1969) and Apollo 10 (May 18, 1969) orbited

the moon and practiced lunar and command module docking before returning to earth.

On July 16, 1969, Neil A. Armstrong, Edwin “Buzz” Aldrin, and Michael Collins embarked on the historic eight-day Apollo 11 mission. While Collins remained in *Columbia*, the command module, orbiting the moon, Armstrong and Aldrin piloted *Eagle* (the lunar module) and landed on the moon’s Sea of Tranquility. Upon landing, they reported to Earth, “Houston, Tranquility Base here. The *Eagle* has landed.” Armstrong was the first human to set foot on the moon. The moment he achieved this major milestone, he stated, “That’s one small step for man; one giant leap for mankind.”

The world watched the successful mission broadcasted live on television. Aldrin joined Armstrong on the surface of the moon, and the two men conducted various experiments, planted a U.S. flag, and deployed a laser beam reflector. Since that time, the reflector has been used by scientists on Earth to conduct long-term observations of the changing distance between Earth and the moon. Armstrong and Aldrin also took the first close-up lunar surface photographs and collected more than 50 pounds of lunar rocks, which they transported back to Earth for study. After spending two hours and 13 minutes on the moon, they returned to *Columbia*, traveled back to Earth, and safely splashed down in the Pacific Ocean.

In late 1969, the Apollo 12 crew became the second to land on the moon. In 1970, the Apollo 13 mission failed. The explosion of an oxygen tank forced the crew to return to Earth without landing on the moon. Between 1969 and 1972, 12 American men walked on the moon and used specially designed tools to allow them to collect samples from the lunar surface. For example, the crew’s spacesuits were designed to protect them from lunar temperatures between -238 and 248°F (-150 and 120°C) and cosmic radiation. Since the spacesuit gloves limited the crew’s dexterity, scientists developed tools with large-diameter textured grips. Spacesuits were not flexible enough to allow astronauts to bend down. To address this limitation, scientists developed tools with long handles, which allowed astronauts to pick things up with a claw-like device from a standing position.

Additionally, astronauts used a rake-like tool to comb the lunar surface and collect samples of diverse rocks. They used a scoop/shovel-like tool to collect

dust samples. To collect samples from beneath the surface ranging in depth from a few inches (or centimeters) to several yards (or meters), astronauts hammered and drilled collection tubes into the ground. The samples they extracted provided researchers with a cosmic ray history of the moon. After the astronauts and the samples returned to Earth, they were placed in quarantine for days to ensure that they were not carrying microscopic substances that might be harmful to the Earth and its inhabitants. The last Apollo mission to the moon was Apollo 17 (1972). In 1975, Apollo 18 (the last Apollo mission) orbited Earth and docked with the Soviet *Soyuz 19* spacecraft. The Cold War-era Apollo-Soyuz Test Project was an unprecedented cooperative mission between American and Soviet astronauts. This type of U.S.-Soviet cooperative venture did not reoccur until after the Cold War.

Due to the rising costs of space projects during a time of pressing national problems, including an economic downturn, the Apollo Project was terminated in 1975. Although the Apollo Project was not the only U.S. space program, its importance was tied to its unprecedented budget and its chief accomplishment of successfully landing Americans on the moon. In political terms, the project showcased American technological superiority and propelled the United States to victory in the Space Race. In fact, the Soviets never made a successful manned moon landing. In this respect, the U.S. flag, which is still on the moon where Apollo astronauts planted it, took on a much greater significance.

Other notable achievements of the Apollo Project included the first photograph of Earth from space and a better understanding of the history and nature of the moon. Throughout the entire Apollo Project, a total of 900 pounds of lunar material were transported to Earth for investigation. Practical mission needs led to technological innovations in tool designs. Later, some of those tool designs entered the consumer market. In addition, the success and prestige of the Apollo Project encouraged future space projects including the manned Space Shuttle program (1972–2011) that conducted many missions in Earth's orbit, and the two unmanned Voyager (1977–) spacecraft that became the first man-made objects to leave the solar system.

ARPANET

The Advanced Research Projects Agency Network (ARPANET) set the infrastructure that would become the Internet. ARPANET began as a network of connected university computers. The ARPANET was funded by the Defense Advanced Research Projects Agency (DARPA). The original intent was to develop a network for military command and control after a nuclear attack.

The computer network was based on telephone lines and required a new technology known as packet switching to move data on telephone lines between computers. After its start-up in 1969, ARPANET evolved into several innovations in the early 1970s such as e-mail, a file transfer protocol that allows data to be sent in bulk, and a remote connecting service for network computers. This network grew to connect universities with defense funding across the nation. When the Defense Department pulled out of the project in 1990, it had laid the groundwork for today's worldwide Internet. Universities continued the old network as the National Science Foundation network (NSFnet) as it had expanded to individuals with the advent of the personal computer.

The roots of the ARPANET go back to the funding of DARPA, which was formed in 1957 as a response to the launching of Sputnik. DARPA was created as a very special research group for the Department of Defense. The name was changed in 1958 to Advanced Research

Projects Agency (ARPA). ARPA had a \$12 million annual budget and much flexibility on spending it. Its first project was to look at a communications network that could operate after a nuclear attack on the United States. This bombproof network would allow distant military centers to communicate. ARPA adapted the early work by Paul Baran of the Rand Institute in the 1960s.

This early network research had been financed by the Air Force. Baran's work was on a packet-switching system that would allow information to be routed on any available electronic lines such as telephone lines. Baran's packet-switching concept was a revolutionary idea of breaking data or messages into packets to flow along available lines; the packets would then be reassembled at the destination machine. This differed from a traditional phone call, which used circuit switching to form a dedicated circuit for the duration of the communication session. Packet switching allows data to flow on a fractured network unable to develop a dedicated or "direct" hookup. Packet switching is a special computer protocol allowing computers to exchange information (network control protocol).

Baran's packet-switching network offered another possibility of connecting universities involved in research for the Defense Department. At the time, even computers in the same room could not talk to each other, let alone computers at different universities. Packet switching along telephone lines would be a necessity to move large blocks of research data. These connections would allow huge amounts of data to be transported between universities. Beyond packet switching, some hardware to handle the messages had to be developed. Since ARPA was a small core group, it contracted out the work to BBN Technologies. To connect distant computers, each location required a gateway computer known as an interface message processor (IMP, or router, as it is known today). The first IMP was built by Honeywell and could service four local computers.

The first network connected computers at the University of California, Los Angeles (UCLA) and the Stanford Research Institute in September 1969. UCLA and Stanford both had Scientific Data Systems (SDS) computers. Initially, after the user typed "login," the system shut down; it took another month to work out the bugs for a message, which was ultimately sent at 10:30 p.m. on October 29, 1969.

By the end of 1969, an IBM 360 at the University of California, Santa Barbara and a DEC at the University of Utah were added to the network. The Massachusetts Institute of Technology was added to the network in March 1970. In 1971, the first e-mail was sent; by 1973, there were over 40 sites, and e-mail made up 75 percent of the traffic, auguring the future of the Internet. To send a message on the ARPANET required a computer to break the message into packets using an Internet Protocol (IP). The packets also received a digital identification, because individual packets might take different paths. Individual packets are routed based on traffic. When the individual packet envelopes reach the destination computer, transmission control protocol (TCP) reassembled the message in the correct order. The network was slow, running at 50 to 200 kilobits per second. The year 1971 also brought the use of a terminal interface processor (TIP) capable of adding over 60 slave terminals to the host computer. By the mid-1970s, huge databases were being passed between universities using file transfer protocol (FTP). The ARPANET had achieved its goal and was supporting both military and civilian research applications. In 1983, the ARPANET was split into the NSFnet and the classified military network (MILnet). ARPANET continued as a communication system between certain research pockets at various universities until most of the IMP routers became obsolete in 1989.

The NSFnet used local area networks (LANs) to link whole universities internally and externally. The NSFnet started to look for more funding as the ARPANET shut down in 1990. In 1991, Senator Albert Gore crafted and the Congress passed the High Performance Computing and Communication Act. The bill created and funded a super information highway for research, which evolved into the Internet of today. Today's Internet is made up of the same infrastructure of routers and protocols. The Internet, regardless of its government origins, has remained firmly rooted in private industry.

Aspartame

Aspartame is an artificial or nonnutritive sweetener formed from the methyl ester of aspartic acid and phenylalanine. G. D. Searle chemist John Schlatter unintentionally discovered the compound in 1965 while developing a new ulcer medication. In 1981, Searle made aspartame, branded as NutraSweet, available for consumer purchase. Aspartame has long been opposed by some public health advocates, but no credible studies have found it hazardous to human health. Aspartame remains one of the most popular artificial sweeteners in the United States.

Saccharine, Predecessor to Aspartame

Saccharine was the first mass-produced artificial sweetener. In 1879, Johns Hopkins University chemist Constantin Fahlberg accidentally stumbled upon the solution while attempting to formulate a new food preservative. After serendipitously tasting the residue of an apparently unremarkable batch, he noted its extreme sweetness and took to calling it “saccharine,” meaning of, or similar to, sugar. Fahlberg quickly sought business partners and tirelessly marketed saccharine to food and beverage manufacturers.

Late-19th-century Progressivism brought the issue of dubious additives into public discourse, and in an era before the 1906 Pure Food and Drug Act, consumers had no idea they were ingesting anything other than cane sugar. The year the act was passed, reformist and chief chemist of the U.S. Department of Agriculture Harvey Wiley submitted a proposal to ban saccharine based on its questionable science. President Theodore Roosevelt personally intervened to keep the sweetener legal, probably because he enjoyed it at the advice of his doctor. (Physicians frequently recommended

saccharine to alleviate ailments such as diabetes or, in Roosevelt’s case, obesity.)

Nonetheless, consumers understood sugar to be part of a wholesome diet. Food and beverage advertisers labeled saccharine-laden competitors as unnatural and nonnutritive. Only mandated World War II-era sugar rationing recovered saccharine from obscurity. Families continued to use saccharine after the war, especially once nutrition science linked excess calories to poor health. By the late 1950s, saccharine was fully commoditized and added to a variety of foods and beverages, and it was also available in packets under the brand name Sweet’n Low.

Aspartame and the Decline of Saccharine

Several factors allowed aspartame to quickly dominate the market once it was commercially introduced in 1981. As early as the 1960s, the implications of a chemical food supply distressed a growing number of Americans. Youth counterculture rejected several aspects of mainstream society, including the inherently artificial nature of saccharine. Others based their concern on scientific evidence. Rachel Carson’s 1962 *Silent Spring*, a widely read exposé of the deleterious effects of DDT pesticide on human health, called into question the chemical processes of American food production. Sufficiently alarmed readers regarded chemical products with deep suspicion.

G. D. Searle executives believed they had found the solution in aspartame once Schlatter had accidentally prepared the sweet solution. The pharmaceutical company branded aspartame NutraSweet and spent more than a decade quietly preparing the product for commercial release. Corporate scientists continually refined aspartame, resulting in a substance free from the bitter aftertaste and high-temperature breakdown of saccharine.

NutraSweet benefited from lengthy product development as the U.S. Food and Drug Administration began intensively reviewing artificial sweeteners. Throughout the 1950s and 1960s, several major studies on the health effects of saccharine had proved inconclusive. A 1977 trial by the Canadian Health Protection Board found a link between saccharine consumption and bladder cancer but only at amounts equivalent to

over 800 diet sodas per day. Still, in March of that year, the FDA announced its intention to ban saccharine on January 1, 1978. Hundreds of thousands of protest letters swiftly flooded offices of the FDA and elected representatives. Writers mocked the extreme research circumstances, promoted their right to choose, and shared deeply personal stories of weight loss attributed to saccharine. The FDA eventually relented to political pressure. Americans might have distrusted saccharine, but they feared the alternative more.

After 1977, Searle understood better than ever the perils of government scrutiny. NutraSweet was subjected to internal safety trials, eventually exceeding all regulatory standards. For added insurance, just as the FDA abortively prepared to ban saccharine, Searle staffed the NutraSweet management team with well-connected outsiders: former congressman and secretary of defense Donald Rumsfeld as CEO, Firestone executive James Denny as CFO, and attorney Bob Shapiro as president. NutraSweet promised a better-tasting, scientifically vetted, and politically untouchable replacement for the embattled saccharine.

NutraSweet first entered the market in powder form in 1981 and was included in prepared food and beverages after 1984. Aspartame became an instant success. NutraSweet profits grew yearly, and in 1985, the brand was acquired by Monsanto. That same year, historian Carolyn de la Peña reports, Americans consumed roughly 800 million pounds of aspartame, and by 1990, more than 1,200 aspartame-containing items lined grocery store shelves. In 1985, NutraSweet also introduced blue packets of Equal sweetener for easy household and restaurant use. The NutraSweet patent expired in 1992, but aspartame sales volume continued to grow. Currently, more than 6,000 supermarket products list aspartame as an ingredient.

Public Health Concerns

Throughout the 1980s, scientific consensus considered aspartame safe. In fact, as the release of NutraSweet neatly coincided with an expanding diet movement, many doctors steered overweight patients toward aspartame to help control weight. As NutraSweet approached its 10th anniversary, however, some public health advocates began voicing their dissent. A slew of

anti-aspartame books and documentaries were released in the 1990s, whose writers ranged from passionate laypeople to concerned physicians. These polemics generally rely upon anecdotal evidence in claiming aspartame responsible for a number of symptoms including headaches, indigestion, dizziness, and even blindness. Current medical and scientific opinion finds no harm in moderate aspartame consumption.

Association for Women in Mathematics (AWM)

The Association for Women in Mathematics (AWM) is a nonprofit organization founded at the Joint Mathematics Meetings held in Atlantic City, New Jersey, in 1971. AWM's mission is to encourage women and girls to study and pursue active careers in the mathematical sciences and to promote equal opportunity and the equal treatment of women and girls in the field. By 2015, the AWM had more than 3,000 members (women and men) representing a broad spectrum of the mathematical community.

In the late 1960s, female mathematicians had been informally organizing, especially in the Boston area at Wellesley College. AWM founding president Mary Gray is largely credited with creating the organization after Joanne Darken, then an instructor at Temple University, suggested that the women of the Mathematics Action Group form their own caucus. Gray is said to have insisted on attending an American Mathematical Society (AMS) council meeting, which until then was open only to men by "gentleman's agreement."

A perhaps apocryphal history says that Gray's answer paraphrased the character Eowyn in *The Lord of the Rings* when she responded, "I am no gentleman." In any case, she stayed at the meeting, which eventually led to the meetings being officially open to observers. The AMS had existed since 1888, with participation by females discouraged until Charlotte Scott had joined in 1891.

Gray's original goals for the organization included equal consideration for admission to graduate school and support while there; female faculty appointments at all levels; equal pay for equal work; equal consideration in assignment of duties and for promotion and tenure; administrative appointments at all levels in universities, industry, and government; and equal access to government grants, positions on review and advisory panels, and positions in professional organizations. While these seem like basic requests today, they were not so in the early 1970s and caused some women to avoid aligning with the group for fear that being considered radical would keep them from being hired.

From the beginning of the AWM, a regular newsletter has been an organizational and communication tool. AWM events at conferences have included scientific talks by female mathematicians and panel discussions on challenges faced by women in the field.

Some events have focused on historical figures or underrepresented groups, such as the panel Black Women in Mathematics organized by Patricia Kenschaft and Etta Falconer and held in Atlanta, Georgia, in January 1978. At that time, of the 12 black women in the United States holding PhDs in mathematics (more, of course, held degrees in mathematics education), 6 were on the panel.

Men compose about 13 percent of the AWM's membership. They become members for a variety of reasons, mostly to show support for women in mathematics. All hold the belief that society stands to benefit from developing the mathematical talents of women.

From the organization's inception, AWM publications, workshops, conferences, and prizes have highlighted outstanding research by women in mathematics and mathematics education and have supported those seeking a career in mathematics through mentoring and network building.

Over the years, AWM activities have grown to include programs for K-12 girls, networks for teachers,

and student chapters for undergraduates and graduate students. The AWM has also advocated for fair treatment and a positive environment for women in mathematics-related fields.

By 2013, AWM's efforts resulted in studies showing that women earned 41 percent of the PhDs in STEM (science, technology, engineering, and math) fields. The downside of the studies showed that women were only represented in 28 percent of tenure-track faculty in those fields in universities across the country. This is a continuing issue, since women in STEM fields earn nearly 33 percent more than those in non-STEM careers, and the wage gap between men and women in STEM careers is smaller than in other fields.

Atari

Atari Inc., founded in Sunnyvale, California, in 1972 by Nolan Bushnell and Ted Dabney, was a pioneer in arcade games, home video game consoles, and home computers. The company's products, such as *Pong* and the Atari 2600, helped define the electronic entertainment industry from the 1970s to the mid-1980s.

Bushnell majored in electrical engineering at the University of Utah, where computer graphics had recently been invented. He found fascination with one

A 1977 Atari computer console with paddle controllers and assorted games, but not the accompanying joystick. (Science & Society Picture Library/Getty Images)

of the first video games, *Spacewar*, developed at the Massachusetts Institute of Technology. During breaks from school, Bushnell worked at a pinball arcade, and eventually he would mesh both those worlds with Atari.

Bushnell and Dabney met in 1969 while working for Ampex and began working on video game ideas, which led to the 1971 release of *Computer Space*. It sold 1,500 units, which was far from a hit, but it made Bushnell and Dabney enough money to start their own company dedicated to the creation and manufacture of what they called coin-operated electronic games. After choosing a name that was already taken by another California company, they switched to Atari because “*ataru*” means “to hit a target” in Japanese and came from an ancient Chinese board game called “go” that

Bushnell enjoyed playing. He had essentially chosen the company’s name from among its strange jargon.

Dabney focused his attention on developing early spot motion circuit technology, which allowed dots to move around on a screen. The company hired a new engineer, Al Alcorn, and he helped it create its first major hit, *Pong*, in 1972. It could be played on video game cabinets in pinball arcades. When they released a home video game of *Pong* in 1975, the company sold 150,000 units. There had been earlier forms of video table tennis games, but *Pong*’s ball sped up as the game went on and pinged off the paddles at different angles depending on where it was hit. The gaps at the top of the screen, actually the result of a quirk in the technology rather than intention, ensured that there

was always a small space for the ball to disappear, ending the game. Also, *Pong* had sound, a feature that previous games had lacked.

Off the success of *Pong*, Bushnell was able to sell Atari to Warner Communications for \$28 million. In five years, sales of Atari home video systems had reached \$415 million, and the company released its first personal computer.

Jack Tramiel, ex-CEO of Commodore, bought Atari in 1984. Tramiel released the mildly successful Atari ST home computer, and sales topped \$25 million in 1986. But six years later, Nintendo brought an antitrust lawsuit against the company and won. Atari tried to deflect that loss by releasing the Jaguar video game system as competition to Nintendo, but the system's exorbitant price dissuaded customers, who tended to buy Nintendo's more economically priced products.

In 1994, Sega game systems traded \$40 million for all of Atari's patent rights, but it did not help right the company. In 1996, a new Interactive division failed, and JTS, a maker of computer disk drives, bought it out, only to sell Atari assets (copyrights, trademarks, and patents) as intellectual property scraps two years later to Hasbro Interactive for \$5 million.

Automotive Technologies (Post–World War II)

Since the end of World War II, the number and variety of technologies incorporated into automobiles have increased significantly while their prewar technologies have been subjected to numerous iterations, variations, and improvements. Each of the systems within an automobile's design relies on a combination of various technologies—many of which have applications in other industries—working in concert to give an

automobile its function. From the manufacturing of its parts and the construction of the vehicle itself to its operation and maintenance, automotive technologies draw from various disciplines of engineering and design to create a finished and functioning product. With the number of automobiles in use globally having exceeded 1 billion in 2010 and projected to double in the coming decades, automotive technologies have significant individual, localized, and global implications, including for human health, economic development, and environmental and ecological health.

As the American economy recovered after World War II, the American auto industry experienced a rapid increase in demand in response as U.S. military forces drew back and soldiers returned from the war. As the industrial sector transitioned back to a peacetime economy, much manufacturing capacity previously dedicated to producing military equipment was repurposed by automakers to meet the growing demand for cars. Facing increased corporate consolidation and market share competition within the industry, illustrated by the dominance of the “Big Three” (i.e., GM, Ford, and Chrysler), American automakers widely adopted the practice of incorporating dynamic obsolescence into automobile design. Also known as built-in or planned obsolescence, “dynamic obsolescence” is a term that denotes the deliberate design of a product to have a limited useful life to promote recurring consumer demand. This practice would, to a great extent, shape the rate and direction of technological advancement in automotive engineering and design, promoting incremental technological improvements bound to social, industry, and market forces.

Throughout the 1950s, various innovations that were devised before and during the war for luxury or military applications were widely implemented by American automakers into consumer automobiles. A comprehensive list of all these innovations would be extensive, but several are especially notable, including the V8 engine, automatic transmissions, and independent suspensions.

A V8 engine is a kind of combustion engine with eight pistons arranged in a V-shaped configuration. Automakers had incorporated the V8 engine, or the overhead valve V8 engine, in automobiles as early as the 1910s. However, it was not until after the war, as average

vehicle tonnage began to increase, that automakers started to offer V8 engines to consumers more widely.

The term “automatic transmission,” also known as “self-shifting transmission,” denotes a type of power transmission system within an automobile that converts and controls the energy output of an engine to the vehicle’s drive wheels without the direct input of a driver. While such transmissions were first developed in the 1930s and incorporated into wartime automobile models, automatic versions were not used in most cars until after the war. Over time, several variations of automatic transmissions have been developed, including continuously variable transmissions (CVTs), semiautomatic transmissions, and the hydraulic automatic transmission. While automakers still feature manual transmissions, notably in performance and racing cars, automatic transmissions reduce the actions and inputs required of the driver.

“Independent suspension” is a term for the system that allows a vehicle’s axles, the shafts used to transfer torque to its wheels, to react to road conditions independently of each other. Beginning in the 1950s, this type of suspension became more common.

These and other technological innovations in the 1950s coincided with the enactment of the Federal-Aid Highway Act of 1956, otherwise known as the National Interstate and Defense Highways Act. Signed into law by then president Dwight D. Eisenhower, it spurred the construction of a network of highways across the nation. Though these new roads brought great benefits, as more drivers took to them, the number of fatal crashes in the United States rose significantly.

Beginning in the 1960s, consumers pressured carmakers to incorporate new safety technologies, including design adjustments to the chassis to better protect the driver and potential pedestrians in the event of a collision; changes to the layout and construction of the instrument panel or dashboard to reduce distractions to the driver; as well as improvements to the transmission, steering wheel, tires, head rests, windshield, etc. Perhaps the most notable safety improvement was the three-point seatbelt system, and later, the airbag. The National Traffic and Motor Vehicle Safety Act passed in 1966, mandating the federal government to establish and enforce traffic and safety regulations.

Innovations in automotive technologies have increasingly responded to government regulation. In the United States, the regulation of automobiles and their parts and technologies are the responsibility of federal agencies, including the National Highway Traffic Safety Administration (NHTSA) and the Environmental Protection Agency (EPA). Both were formed in 1970, during the Nixon Administration. The NHTSA regulates safety standards, and the EPA places restrictions on the chemical composition of combustion engine fuels to control air pollution. For instance, EPA regulations in the 1970s and 1980s prompted the development of the catalytic converter, an exhaust emission control device that reduces the toxicity of a vehicle’s gas exhaust.

Since the 1950s, electronic and computer systems have been increasingly integrated into automobiles. Today, they rely on electronic control units, or ECUs, to regulate and monitor most of a vehicle’s operations. This proliferation of electronic technology has coincided with innovations in computer design, especially the development of semiconductors and their use as transistors in microprocessors. Many electronic and computer systems are standard in cars today, including navigation systems like GPS; Internet and radio; collision detection and warning systems, etc. Autos functions are more automated—there are even autonomous or self-driving automobiles today.

Advancements in battery and energy storage technologies, along with increased awareness of the environmental and health effects of fossil fuel consumption, have prompted a resurgence of hybrid-electric (HEVs) and electric vehicles (EVs). HEVs and EVs rely on much of the same technology that gas-powered cars engines do, but HEVs utilize electric generators in addition to combustion engines while EVs rely on electricity exclusively. HEVs and EVs produce little to no carbon dioxide exhaust or other, more toxic chemicals, and thus they are often seen as reducing the environmental impact of driving.

As automobiles have become ubiquitous, their technologies have increasingly been scrutinized by consumers, government, and the industry itself. Innovations in automotive technologies do not occur in a vacuum; nor are the effects of their usage restricted to the performance of the vehicle.

Baer, Ralph (1922–2014)

Rudolf Heinrich Baer, known as Ralph Baer, is said to be “the Father of Video Games,” as he paved the way for the future of video gaming consoles with his once-ignored vision of future entertainment. Video gaming has grown to be a billion-dollar industry with no signs of slowing down. Before the Xbox One, PS4, and Wii-U, there was the “Brown Box,” the first home video console. Had it not been for Baer’s desire to create an interactive game through an electronic medium, the video gaming industry might not be what it is today.

Baer was born on March 8, 1922, in Germany, where he lived for 16 years before moving to the United States in 1938 in search of refuge from the Nazis. In his first two years in the States, he graduated from the National Radio Institute as a service technician for radios. He served for three years in the U.S. Army during World War II, and then received a BS in television engineering from the American Institute of Technology 1949. Afterward, he joined a succession of electronics firms.

In 1951, Baer worked for Loral Electronics, a company associated with military development. Its chief engineer, Sam Lackoff, asked Baer to build a television set. Baer thought of adding some kind of game to it, but Lackoff felt that this was a waste of time. In 1966, Baer wrote a proposal for how a device could be

hooked up to television set that would allow games to be played on the screen. He described the possibility of action-based, artistic, and instructional games. He pitched the idea to Sanders Associates, his current firm, and it funded his research.

Baer worked with Bob Tremblay, a Sanders technician, to develop the products. After many tests, they finally created the “Brown Box” that allowed people to play multiplayer games such as ping-pong and volleyball on the television screen. The Brown Box, which would later be renamed the “Odyssey” by the Magnavox company in 1971, was the first home video game console.

Baer was awarded the National Medal of Technology by President George W. Bush in February 2006.

Baer’s success continued beyond his Brown Box. He later grew his own business around electronic toys and games, including Milton Bradley’s *Super Simon*. He continued to contribute to the industry until his passing on December 6, 2014. The Academy of Interactive Arts and Sciences gave him the 2015 Pioneer Award posthumously.

Primary Document: Excerpt from Ralph Baer's Four-Page Paper Describing His Plans for Simple Video Games (1966)

*Ralph Baer is known for creating the first-ever video game console back in the late 1960s. This excerpt is from his notes explaining his vision of the video game console, which were read during a patent infringement court case, *Magnavox v. Bally et al.*, consolidated case number 74 C 1030 (1975). In it, he mentions how the console was to connect to the television as well as the types of games to be created for it, such as action, artistic, and instructional games.*

1. Intent

The purpose of the invention is to provide a large variety of low-cost data entry devices which can be

used by an operator to communicate with a monochrome or color TV set of standard, commercial unmodified type. Entry into the TV set is to be gained either through direct connection to the video system (at 2nd detector) or by connection to the antenna terminals, thus substituting the entry device (hereinafter called "generator") for the broadcast TV signal, by modulating an RF oscillator operating on one of the several standard TV channel frequencies, and tuning the TV set to that channel (channel LP for Let's Play). . . .

Bar Code Scanner

Historians have now heralded June 26, 1973, when a pack of Wrigley's Juicy Fruit Gum was scanned at a Troy, Ohio, supermarket, as the beginning of commercial bar codes by enshrining the pack of gum in the Smithsonian. However, the history of bar codes and code scanning goes back to the 1940s. Even though initial capital and equipment investments could be as large as a million dollars, studies showed that there would be a payback in less than three years. In addition, food processors would have to invest heavily in the new technology. The cost of the equipment fell over time, and new applications and savings quickly surfaced. However, progress was hindered by the resistance of unions, manufacturers, and consumers, which slowed overall implementation.

The bar code is a visual code in an optical, machine-readable format. In the late 1940s, Bernard Silver and Norman Woodland of the Drexel Institute of Technology realized that reading product information, such as the price, at the checkout registers of grocery stores—as well as keeping track of sales and inventory—was critical to the profitability of supermarkets. Woodland and Silver received a patent for

their system based on Morse code and an optical reading system adapted from the de Forest movie sound system, which allowed reflected data to be converted into sound. The system had serious commercial limitations, but the patent rights were sold to IBM in 1951 and to Philco and then to RCA in 1963. All of these companies became actively involved in the development of a commercial bar code system. In the late 1950s, railroads tried to use such systems to identify railroad cars but had limited success.

The motivation to fully develop a bar code system came from the National Association of Food Chains, which recognized that it could reduce costs and boost inventory control for supermarkets. In 1966, the association worked with RCA, owner of the Silver and Woodland patent, on developing a system, and Kroger offered to be a test company for it. The industry group also requested the help of other companies working on bar codes such as IBM, National Cash Register, and Singer. In 1973, the RCA system (using an IBM coding label) was successfully tested at Marsh's Supermarket in Troy, Ohio. The IBM code would become the universal product code and the industry standard. The code was split into two halves of six digits each. The first digit differentiated products between those of

Bar code scanners revolutionized check-out processes, the shipping of boxes, and inventory counting. By reading codes in one swipe, productivity increased dramatically. (Bacho12345/Dreamstime.com)

variable and nonvariable weight. The next five digits were the manufacturer's code, the next five coded the product, and the final digit was for control. Pricing was handled in the software. For years, product prices were still marked on them because customers demanded it.

The system was expensive, and the economic studies were mixed. IBM's own studies showed that to fully realize the predicted savings, 70 percent of the store's products had to be coded. The National Association of Food Chains continued its support in spite of questionable economic analyses, pushing for compliance by food manufacturers to reach the 70 percent implementation by the end of the 1970s. By 1980, 8,000 supermarkets had bar-coding scanners. Unfortunately, the equipment cost, customer resistance, and technology

issues did not allow the grocery industry to realize the projected savings.

Simultaneously, other industries and companies were advancing the technology. Computer Identics Corporation was working on the application of codes for manufacturing industries. Its founder, David Collins, had worked in the early 1960s on the failed application of bar codes in the railroad industry. Computer Identics Corporation was using the cutting-edge technology of laser readers by 1970. These scanners were much better than the 500-watt-lightbulb system of the Woodland patent. Lasers could read codes quickly and accurately. Even before the famous scan of a packet of gum, Computer Identics was using its system at General Motors to identify, monitor, and track car axles at manufacturing plants. Engineers might argue that this was the first bar code system in 1969, but it lacked the standardized and uniform code that was being developed for the grocery industry. The laser technology, however, would hold the key to the bar code's full commercial success in the 1990s.

By the late 1990s, the bar code had led to billions of dollars in savings for manufacturers and retailers, the biggest savings coming from improved inventory control, marketing and sales analysis, and monitoring of sales trends. It also helped reduce shoplifting as well as the number of employees. The full implementation of automatic checkout was slow during the 1990s, as there was union resistance, consumer resistance, and the need for good verification systems. After 10 years, the full savings of automated checkout were being realized. Manufacturing use of bar codes for inventory control is also reaching full implementation.

The retail industry continued to advance the technology with QR codes in 2005, which allow cell phone users to read them; they are linked to related Web sites to allow shoppers to compare prices and product information. Applications in the logistics industry for tracking have also been fully implemented. Bar codes have also spread to hospitals and research organizations.

Benerito, Ruth Rogan (1916–2013)

Ruth Rogan Benerito was an American chemist and inventor known for her work related to the textile industry, especially the development of wash-and-wear cotton fabrics. She also had 55 patents and was said to have saved the cotton industry with her discovery of a method for constructing wrinkle-resistant cotton.

Benerito was born in 1916 in New Orleans, Louisiana. She was only 15 when she began at H. Sophie Newcomb Memorial College, which was the women's school at Tulane University. She then received her bachelor's degree in chemistry in 1935 and her master's in physics in 1938. Later, she attended the University of Chicago, where she earned her PhD in physical chemistry in 1948.

Cotton was a dominant crop in the American South, where Benerito was raised in the 1900s. The lightweight and breathable fabric was the material of choice for everyday living. One of the major drawbacks of early cotton fabric is that it would wrinkle easily during washing, which made ironing a mandatory step to make it wearable. Depending on how big one's household was, this chore could take up a big chunk of someone's day when one could be doing something more beneficial—like making money. Synthetic fabrics were later developed, like polyester and nylon, and took a share of the fabric market. Though they could be worn without ironing, they were much less comfortable compared to cotton. A group led by Benerito proposed a chemically treated cotton that would eliminate the ironing process. This method of attaching organic chemicals to cotton fibers is known as “cross-linking.” Benerito and her team made cotton

fabric not just wrinkle resistant but also stain and flame resistant. Wrinkle-free cotton is, in fact, considered one of the most significant technological developments of the 20th century.

During the Korean War, Benerito developed a way to deliver fat intravenously to patients who were too sick to eat. This method was used to feed seriously wounded soldiers at the time and saved many lives.

At the age of 86, she received the prestigious Lemelson-MIT Lifetime Achievement Award for her work on textiles and her commitment to education. For her role in the textile industry, Dr. Benerito was inducted into the National Inventors Hall of Fame in 2008. She later passed away at her home in Metairie, Louisiana, at the age of 97.

Biodiesel

Invented first but then overtaken by the popularity and low cost of diesel fuel, biodiesel is a form of renewable fuel made from vegetable oil or through rendering animal fat. International biodiesel is a fuel composed of mono-alkyl esters of long-chain fatty acids that meet international ASTM D 6751 processing standards. These fuels can be used directly in diesel engines or for mixing with petroleum diesel-based fuels. Currently, biodiesel is used by commercial automobiles in mixed petrodiesel blends, in heavy agricultural and construction machinery, and in local transportation such as short-travel railways. Biofuels are one of the many possible responses to creating cleaner burning fuels, an important, leading global issue in the face of

climate change and the dissipating ozone layer. Oddly enough, biodiesel had been invented before these issues were seen as problems.

Experiments into ways to extract fuel in this fashion had begun as early as the mid-1800s, before gasoline took over the market. Using a process known as “transesterification,” E. Duffy and J. Patrick honed the process using only pure, unprocessed vegetable oil. Then Rudolph Diesel created the first diesel engine in the 1890s, feeling that it would be far superior to the steam engine, which used high-pressure compression to ignite its fuel. He presented an engine powered by peanut oil at the 1900 World’s Fair. This fueled an interest in vegetables as an alternative to petroleum, but the idea faded due to issues with the viscosity of vegetable oils. Also, petroleum-based fuels started to become mass-produced and thus cheaper than biodiesels.

Although biodiesels are normally made from vegetable oils or animal fat, other sources are now being researched. One alternative is the use of algae. A major benefit from using algae is that it does not require farmland or fresh water, because it can be grown in water treatment plants. Also, algae do not consume edible source material that is better used to feed people. Other products being researched include fungi, coffee grounds, and sewage. All of these sources undergo the same process of transesterification for creating fuel.

The process can be done in various ways, including the common batch process, the supercritical process, the ultrasonic method, and the microwave method. The process uses methanol to create mono-alkyl esters. If denser alcohols such as ethanol and butanol are used, the biodiesel can perform at lower temperatures, but the yield from the transesterification is not as high. A by-product of the process is the creation of glycerol, which, because of the recent surge in production of biodiesels, has flooded the market.

In comparison to petroleum-based diesel, biodiesel comes close in energy yield. One hundred percent biodiesel is only 10 percent less efficient than petroleum-based diesel. Biodiesel is also better for lubricating diesel engines. Standard diesel leaves behind sediment, while biodiesel dissolves this sediment and does not create other waste products. Biodiesels do

have a higher flash point of combustion. Depending on its base, biodiesel’s flash point is usually 266°F or 130°C compared to petroleum-based diesel, which ignites at around 147°F or 64°C.

Biodiesel also has a high freezing point and gels at higher temperatures than low-sulfur petroleum gasoline. The freezing point depends on the source; biodiesel made from canola seed has a freezing point of 14°F or -10°C, while that made from tallow has a freezing point of 61°F or 16°C. Biodiesels are completely safe and nontoxic because they are biodegradable, degrading four times faster than petroleum-based diesels.

Biodiesels produce 78 percent less carbon monoxide when made with no sulfur impurities; biodiesels can burn sulfur free, preventing a major contributor to acid rain. They also burn 56 percent less hydrocarbon and are 94 percent lower in carcinogenic properties than standard diesel.

In the United States, there has been an increase in biodiesel use over the last couple decades to combat higher gasoline prices at the fuel pump and reduce the country’s dependence on oil-producing nations. From producing only around 25 million gallons in the early 2000s to around 2.1 billion gallons by 2015, the United States is on track to replace 10 percent of all petroleum diesel fuel by 2022, although it is now considered more as an additive than a complete replacement. Creating blends of the two fuels would reduce the sulfur impurities in petroleum-based diesel while also increasing its lubricity. Blends would also lower the total amount of harmful contaminants in emissions, creating healthier areas for anyone who works in close proximity of said emissions. The rise in electric-powered vehicles might make a dent in the popularity of biodiesels, as much remains in flux regarding the most planet-friendly way to fuel travel and trade.

Primary Document: Statement of Anne Steckel, the Vice President of Federal Affairs of the National Biodiesel Board, to the Senate Committee on Environment and Public Works (2016)

On February 24, 2016, Anne Steckel, the vice president of federal affairs for the National Biodiesel Board, gave testimony on the need for growth in advanced biofuels in the United States, specifically biomass-based diesel. She spoke before the Energy and Commerce Committee's Subcommittee on Energy and Power chaired by Senator James Inhofe and ranking member Senator Barbara Boxer. Steckel's expertise in the field came from years of overseeing legislative issues for several members of Congress and directing government relations for the American Farm Bureau Federation and for Growth Energy, a renewable fuels trade group.

Written Statement of Anne Steckel Vice President of Federal Affairs, National Biodiesel Board Senate Committee on Environment and Public Works United States Senate Oversight of the Renewable Fuel Standard February 24, 2016

Chairman Inhofe, Ranking Member Boxer, and other members of the Committee, I appreciate the opportunity to provide a written statement regarding the Renewable Fuel Standard (RFS) and the EPA's recent action setting annual volume standards.

Our comments today will focus on our continued efforts to grow the Biomass-based Diesel and Advanced Biofuel categories of the RFS. Biomass-based Diesel—commonly referred to as “biodiesel”—includes both biodiesel and renewable diesel, and qualifies as an Advanced Biofuel under the program.

In creating the RFS, Congress and the Administration of President George W. Bush sought to substantially increase domestic renewable fuel production in an effort to reduce our dependence on petroleum, to create jobs and economic activity in a new American energy industry, and to reduce harmful emissions. The law particularly sought to promote the development of Advanced Biofuels—those reducing greenhouse gas emissions by at least 50 percent.

To date, biodiesel is the first and only EPA-designated Advanced Biofuel under the program to reach commercial-scale production nationwide. Since the RFS was created, biodiesel has grown from a niche fuel to a commercial-scale industry with a record U.S. market of nearly 2.1 billion gallons last year, all made from an increasingly diverse mix of resources including recycled cooking oil, soybean oil and animal fats. Biodiesel's growth is proving that Advanced Biofuels are achieving the goals of the RFS.

Those goals are as compelling today as they were when Congress initially created the RFS with overwhelming bipartisan support in 2005. While most of us appreciate the low prices we are currently seeing at the fuel pump, we should not be lured into complacency. All of us know that oil prices rise and fall, often under the influence of nations and cartels that do not have our best interests at heart. We understand that fuel prices will rise again in the not too distant future, and Americans expect our elected officials to work on solutions. We must continue to develop and incentivize alternative fuels to protect American consumers from these price fluctuations, and to ensure that our economy is not overly dependent on a single, globally traded commodity. Doing so requires consistent, long-term policy.

We also must continue to develop new fuels that reduce harmful pollutants, including carbon emissions, which are creating costly public health problems along with tremendous burdens on public infrastructure. And we must incentivize new technologies that create the jobs of the future and keep the United States at the forefront of advances in the energy sector.

The RFS is working to do all of those things in a cost-effective way that helps consumers.

The National Biodiesel Board has worked closely with the EPA, including EPA Administrator Gina

McCarthy, Acting Assistant Administrator Janet McCabe, and their very capable team led by Director Christopher Grundler. We appreciate the EPA's hard work to get the annual process of establishing volume standards back on track from a timing perspective. We look forward to working with the EPA this year to continue to increase the volumes of domestically produced biodiesel, renewable diesel and other advanced biofuels.

Specifically we will be working with the Administration to grow the Biomass-based Diesel program from the 2.0 billion gallons established for 2017, and the Advanced Biofuels program from the 3.61 billion ethanol-equivalent gallons the EPA set for 2016.

The evidence clearly shows that stable, growing biodiesel volumes will help achieve the goals of Congress and the EPA. We believe biodiesel is the cleanest fuel available on a commercial-scale today. According to EPA calculations, which were recently corroborated by similar findings from the California Air Resources Board, biodiesel reduces greenhouse gas emissions by 57 percent to 86 percent when compared to petroleum diesel. It is without question the most successful Advanced Biofuel to date under the RFS, and it has delivered the vast majority of Advanced Biofuel under the program.

Additionally, thanks to the market dynamics of the RFS, biodiesel blends are often available on the market at prices lower than petroleum diesel. Fleets across the country, including the U.S. Navy, confirm this.

Yet in the most recent rulemaking, the EPA finalized a 2.0 billion gallon program for Biomass-based Diesel for 2017. That is slightly less than the 2.1 billion gallons of biodiesel actually delivered under the RFS in 2015, and significantly less than the more than 3 billion gallons of registered biodiesel production capacity in the U.S.

We can do more and we should do more, particularly in a 60-billion-gallon diesel market that continues to grow.

After careful review of industry production capacity, feedstock availability and other factors, NBB will continue to urge the EPA to fulfill the intent of Congress and move forward in the growth of Advanced Biofuels and specifically the Biomass-based Diesel program in a meaningful way that drives investment and production.

Of note, we believe the EPA has significantly underestimated the volume of imports that are already making their way into the U.S. Biodiesel imports to the U.S. have grown sharply in recent years. In 2015 alone more than 650 million gallons of biodiesel and renewable diesel were imported to the United States, up from less than 100 million gallons in 2012. We expect that trend to continue. The EPA's decision to streamline feedstock certification for Argentinian biodiesel, in particular, is widely expected to result in significant new volumes of Argentinian biodiesel coming to the U.S. Additionally we anticipate that already mature or growing biodiesel markets from Asia and the European Union will continue to ship product to the U.S. at increasing levels in the coming years.

We believe more robust volume targets are warranted to help accommodate growing imports while at the same time incentivizing domestic production. Clearly, the intent of Congress in developing the RFS—and expanding it under the Energy Independence and Security Act of 2007—was to generate more domestic production of renewable fuels in the diesel markets and to move toward Advanced Biofuels.

While the final EPA volumes established last year were a step in the right direction, NBB believes the agency was still far from fulfilling the intent of Congress. We believe the EPA must provide for meaningful annual increases to effectuate the statute's requirements and goals.

About NBB: NBB is the national trade association representing the biodiesel and renewable diesel industry as the coordinating body for research and development in the United States. It was founded in 1992, and represents fuel producers, feedstock organizations, fuel marketers and distributors, technology providers and other related businesses.

Biodiesel/Renewable Diesel Background: Biodiesel, renewable diesel, and renewable aviation fuels are renewable, low-carbon diesel and jet fuel replacements. The EPA has determined, based on the lifecycle and greenhouse gas emissions requirements established under the Energy Independence and Security Act (EISA) (P.L. 110-140), that these fuels qualify as Advanced Biofuels under the RFS—in that when compared to petroleum diesel, they reduce

greenhouse gas emissions by at least 50 percent. There are over 200 biodiesel and renewable diesel plants registered with the EPA, representing a combined production capacity in excess of 3 billion gallons.

I appreciate the opportunity to submit comments. If you have any questions or comments, please do not hesitate to contact me at 202.737.8801.

Sincerely,
Anne Steckel

Vice President of Federal Affairs National Biodiesel Board

Birth Control Pill

Oral contraceptives, known as birth control pills, COCP, OC, POP, and most commonly just “the pill,” are generally made up of two synthetically produced forms of hormones that occur in the female body naturally. Synthetic estrogen and progestin (synthetic progesterone) help to regulate a woman’s menstrual cycle. When taken in the appropriate quantities, following a precise timetable, the pill is also very effective in preventing pregnancy. It has shown a 99 percent effective rate: fewer than 1 of every 100 women who uses a birth control pill as a primary contraceptive becomes pregnant. This medical development was more than just a pregnancy preventative; it is noted historically as a seminal step in sexual independence for women, giving them more freedom over their bodies and thus their futures. Thus, oral contraception in the form of a self-administered pill revolutionized birth control options for women and men.

Prior to the development and full-scale release of this contraception form, unwanted pregnancy, religious, and legal barriers were some of the many obstacles to a female’s autonomy over her own body, and even a couple’s enjoyment of sexual intimacy. This medical and social tool is so much a part of American culture that a song by country singer Loretta Lynn in 1975 simply titled “The Pill,” was listed as one of Billboard’s Top 100 country songs.

Today, there are many different kinds of hormonal birth control pills with different levels and types of hormones. Birth control pills are classified as monophasic, biphasic, or triphasic pills (“phasic” meaning by stages or levels), contingent on the amount of hormones released by the pills during the 21 days of a woman’s menstrual cycle. Everything that went into

the pill’s creation and subsequent distribution represents a watershed moment in the history of medicine, women’s issues, sexual freedom, and contraception.

Three pivotal names in the development of the oral contraceptive are Margaret Sanger (1879–1966), Katherine McCormick (1875–1967), and Dr. Gregory Pincus (1903–1967). Margaret Sanger, a staunch supporter of female reproductive rights, helped to underwrite the development of the first birth control in pill form, even raising tens of thousands of dollars for the project. Katherine McCormick, herself holding a BA in biology from MIT and an avid women’s rights activist and philanthropist, helped finance the venture almost singlehandedly. These two dynamic women teamed up with the cutting-edge biologist and scientist Gregory Pincus when, on June 8, 1953, Sanger took McCormick to his small lab outside of Worcester, Massachusetts. With funding from McCormick, in a matter of months, Pincus and his colleagues found that progesterone, which is naturally produced in the body, when used at repeated higher doses on test animals, stopped ovulation.

So, while the use of progesterone was viable as a contraceptive, finding a suitable way to turn it into a pill was not so clear. In what seemed a perfect storm for the creation of the miracle drug, Pincus found that not one but two major drug companies had recently created orally effective forms of synthetic progesterone (progestin). Although birth control as a topic for public conversation and consumption was still very much a sticky subject, both Syntex and Searle laboratories allowed Pincus to use their formulas with his creation and in his initial human studies of the subsequent drug. In 1954, Pincus, along with the well-respected and well-known fertility specialist Dr. John

Rock, successfully conducted the first human trials on 50 women in Massachusetts (Tone 2001).

Additional tests were done outside of the United States, and in 1957, the U.S. Food and Drug Administration (FDA) approved the pill—not as a contraceptive but as an aid for severe menstrual disorders. It was not until 1960 that the FDA approved the first oral contraceptive, Enovid. Dispensing of the pill also required a special effort. David Wagner, an engineer, is credited with designing a dispenser to help his wife remember when and if she had taken her pill. Wagner designed two dispensers similar to those in use today—one circular and one rectangular. While there was initially a bit of copyright infringement as the large drug companies attempted to replicate his design, his model is still predominantly used. The pill was packaged to be dispensed in one of two forms—either for a 21- or a 28-day cycle. For the 21-day distributor, a pill is dispensed daily for three weeks, followed by a week without taking pills. For the 28-pill dispenser, 21 pills are taken, followed by seven days of placebo or sugar pills.

Despite its approval by the FDA, both civil and religious laws prevented its widespread use. Contraceptive use had for many decades been a problematic battleground throughout U.S. history. The biggest opponent was notably the Comstock Law of 1873, which virtually lumped birth control with pornography and prohibited the sale and distribution of birth control, and even materials that mentioned it, throughout the United States. As of 1960, at least 30 states still had Comstock laws in effect. The Supreme Court did not declare the law unconstitutional until 1983, 18 years after the pill had been approved for contraceptive use. Additionally, after the legalization of the use of the birth control pill for the general population, the Catholic Church also took a stance on it when in 1968, Pope Paul VI issued the Church's position paper *Humanae Vitae* ("Of Human Life"). The position piece put forth to followers that the birth control pill was sinful and artificial and therefore not approved by the Church.

Despite this, the pill as a medical tool was quickly embraced by American society. By the end of 1962, an estimated 1.7 million American women were taking Enovid to regulate their cycles and help prevent severe cramping, and curtailing pregnancy as a side effect. After three years, the number almost doubled to 2.3

million. However, in 1964, the pill was still controversial and illegal in eight states. Despite its effectiveness and widespread use, it was not until 1965, with 6.5 million American women on the pill and five years after it had been approved as a contraceptive, that a Supreme Court ruling gave married couples in many states, but not all, the right to use this easy and effective method. In *Griswold v. Connecticut*, the Supreme Court struck down state laws prohibiting contraception for married couples. Nevertheless, it was not until 1972, through the case of *Baird v. Eisenstadt*, that the Supreme Court legalized birth control for all people in the United States whether married or not.

The use of the birth control pill had significant impact beyond controlling contraception. As a result of the autonomy over their reproductive functions, more women attended and graduated from college in the 1970s. The pill is also attributed changes in the socio-moral atmosphere in the United States during the late 1960s and throughout the 1970s. There was an appreciable rise in the rate of single mothers, more unmarried couples were living together, and overt displays of sexuality became more prominent in the media.

The history of the birth control pill in the United States has had many ups and downs. Early in its release, the possibility of thromboembolic disease, which includes blood clots and pulmonary embolism, was recognized and reported in 1961. In 1969, the book *The Doctor's Case Against the Pill* created panic and fear when it was revealed that side effects also included the possibility of heart attack, stroke, depression, weight gain, and loss of sexual desire. Continued inquiries into the safety of this medication resulted in the creation of a lower estrogen dose pill in 1988 and the removal of the original higher-dose pill from the market. This lower dose has been noted to have even more beneficial health benefits, such as a lowered risk of ovarian cancer and pelvic inflammatory disease. Additionally, the estrogen-based pill may have contraindications with certain antibiotics, natural supplements, and antianxiety medications. Nonetheless, the benefits have outweighed the consequences, socially and legally, in the pill's history. By 2000, it became a federal mandate that prescription contraceptives must be covered under insurance offered by employers, no matter the employers' beliefs.

Oral contraception in pill form is no longer as simple as the Enovid first prescribed and approved for public consumption with its 21- or 28-day cycle. The market has grown to include controversial oral contraceptives such as the morning-after pill, also known as Plan B and Seasonale, which limits the number of periods that a woman has per year to four. In addition, oral contraceptives are sometimes prescribed as medication for mild or moderate acne.

Bomb Disposal Robots/Units

Because they are not autonomous, the term “bomb disposal robots” is more of a nickname than a technical name because the devices currently in use are not technically robots. Since their creation in the early 1970s in England, such bomb disposal units have been a key tool for military, law enforcement, and even farming in that they can go into places too dangerous for humans and provide visual feedback as well as often solving situations via remote control.

In 1972, a retired Royal Tank Regiment officer, Peter Miller, created the first bomb disposal unit after the deaths of too many Royal Army bomb defusers during attacks by the Irish Republican Army (IRA). For the main body, he used an electric wheelbarrow and attached a grappling hook controlled by a rope and set of pulleys. The unit’s main function was to tow car bombs to a safe detonation location. Later additions to the device included the ability to shoot a stream of water to short-circuit the bombs.

The reliance on ropes and pulleys proved an early flaw with this unit; later producers used

telecommunication cables, then remote control, and finally a device well known to many millennials—a video game controller. The earlier devices also had traction issues, often falling over while towing vehicles. Dual tank treads or multiple wheels were employed to catch the unit and right it as it tilted.

Currently, the most commonly used remote-control bomb disposal unit in the United States is the Andros. Designed by a subsidiary of Northrop Grumman called Remotec, the unit is used in various fields from military use to law enforcement or special weapons and tactics (SWAT). The Andros has been made into different units, each varying in weight and use. The largest, weighing in at 810 pounds, is the “Wolverine” and is used primarily for military bomb disposal operations. The Andros Mark V-A1 is a variant of the basic model, weighing in at 790 pounds, with four cameras and a manipulator arm. This model notably caught national attention on July 6, 2016, when it was used to kill a suspect who had killed multiple police officers in Dallas, Texas. Instead of defusing a bomb, the robot was deployed to deliver a bomb that detonated in the vicinity of the suspect.

With advancements in computer systems, in the last couple decades, these units have seen the addition of various sensors to show the human controller what the robot sees; radioactive, x-ray, and thermal sensory equipment for different types of bombs; a claw that can move in multiple dimensions to grab objects; wire cutters; drills; and even firearms.

Brill, Yvonne Madalaine Claeys (1924–2013)

The inventor of a satellite technology that revolutionized satellite systems by boosting fuel efficiency, Yvonne Madalaine Claeys Brill is also known for her contributions to NASA while raising three children.

Brill was born in St. Vital, a suburb of Winnipeg, Manitoba, on December 30, 1924, to Belgian immigrants. When Brill applied to the University of Manitoba's engineering program, there were no accommodations for women at its mandatory outdoor engineering camp, so they were not admitted. Undeterred, Brill studied mathematics and chemistry instead, earning top marks in both programs. Despite the fact that she still lacked an engineering degree, Brill landed a job with Douglas Aircraft in Santa Monica, California. She later earned her master's degree in chemistry at the University of Southern California.

Working with Douglas aircraft and their satellite project, Brill cofounded the Rand Corporation, an early research center and one of the first think tanks for the U.S. Air Force. Here, Brill worked on some of the first satellite designs.

In 1951, she married William Franklin Brill, whom she had met at a talk by famed chemist Linus Pauling. The new couple moved to New Jersey, where Yvonne Brill took a rocketry job at Wright Aeronautical. In 1958, Brill left that company to care for her children but continued working part time as a consultant.

In 1966, Brill returned to work full time at Radio Corporation of America (RCA)'s rocket subsidiary, RCA Astro Electronics. In 1972, she patented a dual-thrust level monopropellant spacecraft propulsion system for satellites, which overhauled satellite propulsion. Previously, electrostatic, or ion, engines would be used after initial takeoff to correct a satellite's flight path to get it into orbit—or perhaps even while the satellite was already in orbit, to maintain its path.

Brill's system used a monopropellant and a manifold system to distribute fuel to different sets of thrusters for different types of thrust, reducing weight and, in turn, improving fuel efficiency. Other names for this system include "hydrazine resistojet" and "electro-thermal hydrazine thruster." This technology is still in

use by almost 120 spacecraft, including satellites that handle worldwide phone service, long-range television broadcasts, and more.

In 1980, *Harper's Bazaar* and the DeBeers Corporation awarded Brill with their Diamond Superwoman award given to women over 40 who had stopped their careers to raise children and then successfully returned. The next year, Brill left the RCA Corporation and joined NASA, where for two years she was manager of the Solid Rocket Motor Program in the shuttle project. In 1986, Brill worked in London at the International Maritime Satellite Organization as propulsion manager for their satellite system.

Though she retired in 1991, Brill continued to consult on propulsion systems of orbiting communication satellites. She served on various panels and boards related to spacecraft technology, including the Mars Observer Spacecraft, which launched in 1992.

In 1986, Brill received the Society of Women Engineers' Achievement Award. She was then elected fellow of the American Institution for Aeronautics and Astronautics and made a member of the U.S. National Academy of Engineering. Brill became an inductee into the Women in Technology International Hall of Fame in 1999, and in 2001, NASA awarded her its Distinguished Public Service Medal. In 2010, she was inducted into the National Inventors Hall of Fame, and in 2011, President Obama awarded Brill the U.S. National Medal of Technology and Innovation. Brill passed away due to complications from breast cancer in 2013.

Primary Document: Yvonne Brill's Patent for New Jet Propulsion Technology (1974)

Yvonne Claeys Brill is famous for two things: engineering for NASA, because she was the first woman to do so, and patenting new jet propulsion technology that is still in use today. Previously, the most attractive method for flight correction in a satellite in orbit was an ion engine, but there were many types of fuel and mechanisms needed in that system that weighed down the satellite and meant less room on it for equipment. Brill invented a new system in 1972 that used the same propellant for all jet propulsion in the satellite from large to small thrusts alike, boosting efficiency and revolutionizing jet propulsion.

United States/Patent I 1191 1111 3,807,657

Brill - [45] Apr. 30, 1974

PROPULSION SYSTEM Attorney, Agent, or Firm—Edward J. Norton; Joseph D. Laza

A flight auxiliary propulsion system for velocity trim, station keeping, momentum adjustment for a space craft comprising rocket or reaction motors, also designated thrusters, utilizing thermally decomposable

monopropellants such as hydrazine and other derivatives, thereof hydrogen peroxide, and isopropyl nitrate. The thrusters are arranged in a distribution or manifold system so that one set of thrusters provides for relatively large thrusts of force in the order of 1 to 5 pounds and another set of low force thrusters in the millipound range. The large thrusts are developed by the catalytic decomposition of the monopropellant into a thrust chamber and through a throat and expansion nozzle to the ambient externally of the spacecraft. The low level thrusts are developed by heating catalytically of thermally decomposed monopropellant by electrical heating elements more commonly known as resisto-jet elements. Dual thrust levels a controllable may also resisto-jet elements. Dual thrust levels may also be achieved by a common motor with a controllable resisto-jet and variable a common throat-area control.

Brown, Marie Van Brittan (1922–1999)

Marie Van Brittan Brown invented the first home security system, which she patented with her husband in 1966. Born in Queens, New York, in 1922, Brown first worked as a nurse. She married Albert Brown, an electronics technician. A combination of her late hours and rising crime in Queens encouraged Marie Brown to think about home security. This problem was exacerbated by the slow response time of police to black neighborhoods in Queens.

Brown devised a system of three peepholes drilled at different heights on a door to meet the different heights of users, from tall adults to small children. A camera, a monitor, and a microphone complemented the peepholes, as did an alarm that connected to the local police station. The camera allowed those inside the home or apartment to see a person outside the door, with the image projected to an in-home monitor not unlike a computer monitor. The microphone allowed those inside the house or apartment to query those outside the door. The system also had a remote-control door latch

that locked or unlocked a door. Marie and Albert Brown called the invention a “Home Security System Using Television Surveillance” and patented it in 1966. Brown never found a commercial manufacturer for it, but her security system is the basis for modern home security systems, and they remain similar to it.

Albert and Marie Brown had two children. They lived in Queens their entire lives. Their daughter Norma emulated her mother and became both an inventor and a nurse. Marie Brown died in Queens, New York, in 1999.

Bulletproof Vest/Kevlar

Kevlar is a man-made material that consists of a light-weight fiber. It is known for having five times the strength of steel as well as being heat resistant. It is the material used to create body armor, like the bulletproof vest, that is resistant to weaponry while still being light enough to wear. Kevlar was fabricated in 1965 by Stephanie Kwolek (1923–2014), who had been studying chemistry for the DuPont Company. At the time, the company had been looking for a material to replace the steel used to line tires.

Kwolek noticed the strength of polymer structures. A polymer is a substance with a chain-like molecular structure that contains multiple similar units bonded together. Kevlar polymer is synthetically altered so that it can be formed into a straight chain, which is then spun into fibers. The result is an ultra-tough chemical bond. When the fibers are amassed into this material, it has been known to take bullets from point-blank range.

After the creation of the bulletproof vest, Kevlar fabric took the world by storm. Today, it is used in hundreds of products worldwide for protection in industries including motorcycle safety equipment, space programs, commercial airlines, and in naval ships, where it is found in highly durable ropes. Even some clothing has Kevlar for minor protection against cuts and scrapes. Kevlar is directly responsible for saving the lives of tens of thousands of people as well as the development of many new technologies that have made life both safer and easier for the average person. That being said, there is still room for improvement in Kevlar products.

Due to its chemical makeup, Kevlar is often vulnerable to environmental conditions. It absorbs water, which can weigh down wearers; it can also be difficult to compress and cut, and it requires specialty equipment to alter. Pragmatically, the stiffness of the fibers can be uncomfortable to wear and can cause a loss of motion in some circumstances. The result can be dangerous or even fatal for those in situations where they need to be mobile, such as police officers.

Just because Kevlar is stronger than steel does not mean it is invincible. Bulletproof vests made of Kevlar do not protect against blunt-force trauma. If a bullet is

fired into it at point-blank range, it still may do damage, even if it does not penetrate the skin. To prevent injury, some companies are testing combinations of Kevlar with thickening fluids that harden on impact and would absorb the damages that regular Kevlar cannot stop.

Carson, Rachel (1907–1964)

Marine biologist and conservationist Rachel Louise Carson is considered the mother of the American environmental movement. She is best known for her 1962 book *Silent Spring*, which brought the environmental concerns associated with the pesticide DDT to the American public. *Silent Spring* and her other writings are credited with advancing the national and even global environmental movement. The book led to a nationwide ban on DDT as well as other pesticides and inspired a grassroots environmental movement that led to the creation of the U.S. Environmental Protection Agency.

Carson was born in 1907 on a 65-acre farm near Springdale, Pennsylvania. She was an avid reader and writer from a young age. At age 11, she had her first story published. The stories that she read and wrote

mainly had to do with the natural world, particularly the ocean. After high school, she attended the Pennsylvania College for Women, today known as Chatham University. She began her university career as an English student but switched to biology later, though she continued to write for the school's student newspaper and literary supplement. She graduated from the Pennsylvania College for Women in 1929 and then went on to study zoology and genetics at Johns Hopkins in the fall of 1929. She earned a master's degree in zoology in 1932 and had intended to continue for a doctorate, but she was forced to leave Johns Hopkins in 1934 to support her family. In 1935, her father died, leaving Carson to care for her mother. In 1937, Carson's sister, Marian, died. Marian's two daughters went to live with Carson and her mother, making her financial situation even more strenuous.

Carson accepted a temporary position with the U.S. Bureau of Fisheries in 1935 to help with the finances. In 1936, she became the second woman ever to be hired for a full-time professional position for the Bureau of Fisheries as a junior aquatic biologist. Carson rose within the Fish and Wildlife Service and was the chief editor of publications by 1949.

By 1952, Carson had decided to make the transition to writing full time. Her earlier trilogy of novels, *Under the Sea Wing*, *The Sea Around Us*, and *The Edge of the Sea*, began her career as a bestselling author. *The Sea Around Us* was her most critically acclaimed work before *Silent Spring*. The books focused on the life in the ocean and coastal ecosystems. In 1953, she met Dorothy Freeman (1898–1978) after moving with her mother to Maine's Southport Island. Though Freeman was married, the two developed a close emotional bond that endured until Carson's death. The same year that she met Freeman, Carson adopted Roger Christie after his mother, one of her sister's daughters, died.

Silent Spring was published in 1962. Carson had been interested in how pesticides were affecting the environment since the 1940s because of the recent decline in the bird populations and the Great Cranberry Scandal of 1957, when cranberries were found to contain high levels of the herbicide aminotriazole. She was in the middle of her work on *Silent Spring*

Rachel Carson, seen here reading in her backyard, sounded the alarm for climate change in 1962 in her book *Silent Spring*. She is credited with jump-starting the environmental movement and helping found Earth Day. (Alfred Eisenstaedt/The LIFE Picture Collection/Getty Images)

when she learned that she had multiple cysts in her breasts, which necessitated a mastectomy. By December 1960, Carson had discovered that the tumor was in fact malignant and the cancer had metastasized. Her illness made her work on *Silent Spring* all the more difficult. The book was published first in serialization in *The New Yorker*. This, coupled with the fact that the book was selected for the Book of the Month, meant that an unprecedented number of Americans were exposed to environmentalism for the first time.

The book was not without critics. The chemical industry that made pesticides, backed by conservative politicians and organizations, attacked her for hampering industry and agribusiness. The attacks on Carson

and her work were so vehement that they eventually backfired. The book inspired grassroots environmental activism and eventually the phaseout of DDT and other dangerous chemicals. The Environmental Protection Agency was also created because of some of the concerns that Carson brought out to the public in *Silent Spring*.

Weakened by cancer and radiation therapy, Carson died of a heart attack in 1964 in her home in Silver Spring, Maryland. Today, Carson's work is seen as the basis for the modern environmental movement and ecofeminism.

Chlorofluorocarbons (CFCs)

Chlorofluorocarbons (commonly known as CFCs) are a class of organic compounds containing carbon, chlorine, and fluorine. First discovered in the 19th century, they were used widely during the 20th century in a number of industrial and consumer applications (such as refrigeration and aerosol propellants). After the discovery that these gases were breaking down the planet's ozone layer, their manufacture was discontinued.

The first chlorofluorocarbons were synthesized in the late 19th century by the Belgian chemist Frédéric Swarts, but it wasn't until the 1920s that chemists realized the commercial applications of CFCs. A research team at General Motors headed by chemist Thomas Midgley, who also invented leaded gasoline, invented a new chlorine-based refrigerant that GM began manufacturing in 1930 under the name "Freon."

Freon is nonflammable, stable, and less toxic than refrigerants like ammonia. It rapidly became the most popular refrigerant chemical in consumer use. Other CFCs became popular for their ability to produce foam in insulation and packing materials, as cleaning solvents for electronics, and as aerosol propellant after the invention of the aerosol spray can in 1941. As refrigerators, automobiles with air-conditioning, aerosol cans, and other CFC applications became more popular, CFC production rose from less than 100,000 tons in 1950 to nearly a million tons in 1974.

In that year, chemists F. Sherwood Rowland and Mario Molina of the University of California, Irvine announced that chlorofluorocarbons could rise slowly into the upper atmosphere, where they would react with the atmosphere's ozone layer and break it down. The chlorine in CFCs reacts with ozone to create chlorine monoxide, which itself breaks down. A single chlorine atom in the ozone layer destroys 100,000 ozone molecules. The chemists further declared that at current production levels, CFCs would destroy about 10 percent of the ozone layer within a century. The ozone layer absorbs as much as 99 percent of the ultraviolet light reaching the earth from the sun. The loss predicted by Rowland and Molina would render the earth's surface virtually uninhabitable for most of the life-forms exposed to sunlight.

By the end of the year, public awareness of this announcement was growing, and within a year, aerosol can sales were down 25 percent. Despite intense lobbying, in May 1977, the Environmental Protection Agency and other U.S. government agencies ordered CFC manufacturing to halt in the United States by the end of 1978. The early successes for the anti-CFC movement sputtered out, however, as industrial firms began pushing back, especially after a Republican administration took office in 1981.

By 1986, CFC production had reached a new height of over 1.2 million tons of annual production. By this point, the scientific consensus on CFC production was great enough to overwhelm many other political considerations. In 1985, 20 nations signed the Vienna Convention, which established the groundwork for an eventual ban on CFCs. That same year, it was discovered that the ozone layer over Antarctica had diminished by over two-thirds. The "ozone hole"

dramatically showed that ozone depletion was a real threat to human and indeed to all life.

In 1987, an international conference in Montreal led to the ratification of the Montreal Protocol, which committed every nation in the world to reduce CFC production by half by 1998 and to completely cease new production by 2000. Later meetings sped the final phaseout date up to 1996. Follow-up meetings led to commitments to phase out a related class of chemicals, hydrochlorofluorocarbons. The Montreal Protocol was extremely successful; ratified by every nation on earth, it has also been adhered to with remarkable strictness. Only a small amount of CFCs were manufactured after 1996 for medical and research purposes; the medical exemption ended in 2008. It is now predicted that the ozone layer will return to its former size sometime after 2050.

Climate Change

Climate change (or global warming), a controversial issue, is widely considered by the scientific community to have been caused by the use of industrial technology, yet technological innovations may hold the key to addressing its environmental challenges. Even though the societal debate on the cause (or causes) of climate change is far from over, the prevailing view of policy makers has been that humanity has caused negative climate change and therefore, it is our responsibility to fix the problem.

Both surface and satellite temperature readings have confirmed that the average temperature of the earth has risen in the last two centuries. In fact, the

warmest five-year period on record was 2011 to 2015. However, the identification of the cause (or causes) of the climate change have remained controversial. Most scientists believe that human activity, most notably the burning of fossil fuels since industrialization in the 1800s, is to blame. However, a small minority has maintained that just because industrialization and global warming happened during the same time frame does not prove that one caused the other. In fact, Earth data from the past 600,000 years reveals a pattern of rising temperature before carbon increases—not after. These scientists also maintain that the earth’s climate is too complex (with too many known and unknown variables) to rule out natural causes as the main driving forces behind climate change.

In 2007, former vice president Al Gore was awarded the Nobel Prize for his efforts to convince the public that climate change is man-made. In *An Inconvenient Truth*, a 2006 documentary film, Gore stated that global warming was melting the polar ice caps at such a rate that water levels could rise by 20 feet by the next century, leaving parts of the United States under water. In 2009, hackers posted excerpts of online of e-mails and data from climate scientists working at one of the most respected and influential climate science research institutions in the world, the University of East Anglia’s (UEA) Climate Research Unit in Norwich, England. The “Climategate” excerpts gave the impression that scientists might have manipulated certain data to support evidence of global warming. Conspiracy theorists speculated on a possible motivation for this type of deception: researchers need funding, and only researchers who identify problems that need to be fixed get it. However, in 2010, a review group of scientists from many countries concluded that, in spite of some errors, UEA’s conclusions about climate change were sound.

In spite of disagreements and controversies, most world leaders have accepted the interpretation of human-caused climate change. According to this view, the negative side effects of climate change have included droughts, floods, and other severe weather. Most of the carbon dioxide in the atmosphere is pumped out by factories. Over the years, developing nations have attempted to catch up to developed nations in an attempt to improve living standards for their people by

building and running factories. Consequently, in spite of environmental concerns, most developing nations have opted to ignore emission restrictions.

The United States ranks as one of the biggest air-polluting developed nations in the world. According to the U.S. EPA, in 2014, carbon dioxide accounted for 81 percent of greenhouse gas emission in the country, and American industries, including farming and electricity production, accounted for 60 percent of all air pollution. Even though most American pollution is caused by industry, the American trend has been to prioritize public initiatives usually driven by assurance in the ability of new technologies to solve problems.

Since most energy plants run on fossil fuel, environmental campaigns have attempted to convince Americans to use less energy. In this regard, policy makers have promoted the construction of energy-efficient homes with energy-efficient lightbulbs and energy-efficient appliances. A negligible percentage of Americans have made the switch to clean energy sources, including the use of solar and wind energy, to run their homes. Automakers have made various types of “green” automobiles. A growing percentage of Americans have purchased automobiles that run on alternative fuel such as natural gas (which produces less carbon dioxide than gasoline) or hydrogen (which produces no carbon dioxide).

Since the 1980s, automakers have sold more popular flexible-fuel vehicles that run on a gasoline-ethanol blend. However, ethanol has produced far fewer advantages than advertised. Ethanol is usually produced from corn, and the tractors that are used to plant and harvest it burn fossil fuels. In like manner, the large trucks that transport ethanol to gas stations burn fossil fuels. In the meantime, American industries continue to account for most American-produced carbon dioxide. Although technological innovations have produced alternative energy sources—including hydroelectric dams, which capture energy from moving water; geothermal plants, which use heat from deep inside the earth to generate steam to make electricity; and wind turbines, which use the natural air flow to produce energy—most American industries continue to burn fossil fuel.

On the world stage, two cutting-edge technologies to aid humankind in fighting human-caused climate

change have been proposed: carbon capture and storage (CCS) and solar radiation management. The CCS system separates carbon dioxide from other gases that are emitted from a factory and then funnels the carbon dioxide through a pipeline (or transports it by ship). The gas is then deposited miles below the planet’s surface. However, as of 2015, CCS was still too expensive to be practical, and it had only been tested at a handful of sites. Solar radiation management is a theoretical concept. The idea is to mimic the natural phenomenon that occurs after volcanic eruptions as sulfur spewed into the atmosphere blocks sunlight; that is, to replicate the phenomenon by spewing aerosols into the sky that would then reflect the sun’s rays away from earth and into space, giving the earth an artificial sunscreen. However, most scientists are hesitant to deploy such a method, because there is no way of knowing what it might do to the earth’s complex climate system.

In 1997, representatives from more than 100 nations met at Kyoto, Japan, to negotiate the first international climate change agreement. The Kyoto Treaty required industrialized nations to cut their greenhouse emissions by 5 percent below 1990 levels by 2012. On the other hand, the treaty did not restrict emissions in developing nations (including China). Although the treaty had initial support from President Bill Clinton, the U.S. Senate rejected it by a vote of 95–0. China and the United States were the two nations most responsible for greenhouse emissions. With these two nations out of the agreement, the treaty lost momentum. It took eight years for participating countries to ratify the treaty in 2005. However, by 2011, some participating nations, including Canada, Russia, and Japan, abandoned the treaty. Critics assessed that the treaty had been a failure. However, more optimistic activists viewed the treaty as a critical first step. They pointed out two important accomplishments of the treaty: it had led to the creation of the first international system for monitoring emissions, and it had encouraged nonparticipating nations to pass their own emission laws. As 2012 approached, some participating nations, including Peru and Djibouti, agreed to extend the agreement to 2020. However, by 2014, only 17 out of 144 nations needed for ratification of the extension had signed.

Building on lessons learned from the Kyoto Treaty, in 2015, leaders met in Paris, France, and signed an agreement to reduce the buildup of greenhouse gases. Leaders from developing nations asked leaders from developed nations to help pay for floods and droughts. On behalf of the United States, President Barack Obama donated a \$500 million grant to the Green Climate Fund to help developing nations that were committed to agreement. By 2016, the United States and China were responsible for 40 percent of global emissions. Although neither of the two nations signed the Paris Agreement, they promised to sign it at some time in the future. In all, 196 nations adopted the agreement to limit global warming to the relatively safe level of 3.6°F (2°C). In 2016, four world cities—Paris, Madrid, Athens, and Mexico City—announced they would ban diesel vehicles by 2025.

CO₂ Welding

Welding is a fabrication process in which two materials are joined by fusion. There are various forms of welding, including oxy-fuel welding, arc welding, and others. In 1953, Lyubavskii and Novoshilov invented CO₂ welding. CO₂ welding became so popular because

it was one of the more affordable ways to weld, which made it preferred for welding steels.

Tools showing signs of forge welding (heating metals and pounding them together) can be found as early as the Bronze and Iron Ages, particularly in Europe and the Middle East. In 1800, two men, one English, the other Russian, nearly simultaneously invented electrical arc welding. Advances in this type of welding occurred throughout the 19th century. In the late 1800s, gas welding was invented, though arc welding was far more popular. Nonetheless, the discovery of gas fuel welding was a key step for the invention of CO₂ welding.

CO₂ welding is where the wire used to weld, wound into a coil, is fed into the welding torch automatically by a motor. The welding wire reacts, becoming electrified through the contact tip, which then becomes the electrode that strikes an arc between itself and the base metal. The arc heat melts that piece of welding wire and the base metal, joining pieces of base metal together. To prevent the weld metal from being affected by oxygen and nitrogen in the air, CO₂ gas is used to shield the weld pool. The CO₂ is provided from the nozzle of the welding torch.

CO₂ is the prevalent reactive gas used in welding because it is the only gas that can be used in its purest form without having to add an inert gas. An inert gas has very low reactivity with other substances. The use of fewer gases is less expensive. There have been many advancements in CO₂ welding, including the introduction of electrode wires with smaller diameters, which makes it more convenient to weld thinner material. This innovation led to the short-circuit variation, which includes micro-wire welding, short-arc welding, and dip-transfer welding.

Commodore 64

The Commodore 64 (C64) computer was introduced in January 1981 by Jack Tramiel, the president of Commodore International. The Commodore 64 became one of the bestselling computers in history because it was significantly more affordable and powerful than any other personal computer on the market at the time.

Though the C64 was originally planned as a video game console, the company expanded plans for the personal computer to replace an older product line. Commodore kept costs down by manufacturing the integrated circuit design and random access memory (RAM) chips in-house. Commodore's competition came primarily from the equally revolutionary Apple II. The two computers represented different approaches to personal computing. The Apple II featured an open architecture system that allowed for upgrades, whereas the C64 was a closed system with a number of ports that allowed for plug-ins like external drives, printers, and modems.

Manufactured from 1982 to 1992, the C64 was on the forefront of the personal computer revolution of the late 20th century.

Comsat/Intelsat

Comsat is a global telecommunications company designed to provide satellite communication services approved by the Communications Satellite Act of

1962. This Act allowed the commercialization of satellite communications in cooperation with other countries. When President John F. Kennedy signed the Act in direct response to the success of the Russian satellite program, it created a new, private company to develop and operate the planned global satellite system. Comsat then became first commercial satellite system operating in the private sector.

Two years later, Comsat contracted Hughes Aircraft Company, founded by inventor Howard Hughes (1905–1976), to design and create its first operational satellite. Known first as Early Bird and later as Intelsat I, engineers designed this satellite for geosynchronous orbit, or the ability to follow the rotation of the earth and in a fixed position over a particular location on the surface.

The success of Comsat nudged the creation of a new private company, Intelsat (International Telecommunications Satellite Consortium), in August 1964. Including 15 allied countries, this multinational organization represented all their interests and became the main source of income for Comsat in the decades to follow. Comsat was the U.S. representative of Intelsat and was selected as manager of Intelsat on behalf of the 15 countries involved.

In April 1965, Intelsat I launched, traveled over 22,000 miles above the earth, and took a permanent position in geosynchronous orbit above the coast of Brazil, making live television broadcasts available across the Atlantic and increasing international telephone capacity by nearly two-thirds.

Comsat then connected satellite coverage between the United States and Europe and looked toward providing full global coverage. A month after Intelsat I was launched, the Federal Communications Commission tasked Comsat with constructing and operating earth stations to broadcast information for international communications.

In 1965, effort was underway to begin the development of the second generation of Intelsat satellites, the Intelsat IIs, intended to provide communications support for NASA's Apollo program. A year later, Comsat experienced its first major setback when the first Intelsat II satellite failed to reach geosynchronous orbit. The second launch in 1967 succeeded in creating the first full satellite coverage over the Pacific

Ocean. In 1968, Comsat began producing Intelsat III, and in 1969, one of the Intelsat III satellites successfully placed in geosynchronous orbit over the Indian Ocean marked the first time that humanity had connected the entire globe with full satellite coverage.

During the 1980s, Comsat entered the entertainment industry through the use of fiber-optic networks. Many cable networks had used ground-based networks instead of satellite networks, and this threatened Comsat's primary business, which was transmitting television media through satellites. This made the need to diversify its services more apparent, leading to Comsat acquiring a majority ownership of the Denver Nuggets.

Comsat entered the 1990s owning three primary business types: international communications, technology services, and entertainment. Today, Comsat and its industry partners include the U.S. military, which now leases satellites from Comsat.

Curanderas

Curanderas are female spiritual healers of Latin American descent who practice faith and bodily healing in rural and working-class areas of North and South America. *Curanderismo*, or faith healing, has a long history stemming from indigenous Latin American healing practices, Judeo-Christian beliefs, Hispano-Arabic philosophies, and Western medical traditions.

While practitioners of *curanderismo* can be male or female, *curanderas* specifically function as cultural matriarchs for Latino communities, especially in the United States.

Curanderas work under the assumption that spiritual unease can manifest as physical ailments and believe that the power to heal is a gift from God. They are often sought out by patients who are poor, uninsured, or undocumented and those who have not found success in alleviating their symptoms through traditional Western medicine, distrust Western health care workers, or believe that there are supernatural causes for their illnesses. Though traditionally, patients are not charged for treatments, many give thanks by donating food, clothing, and housewares.

The *curandera* believes in prayer and her own touch, along with herbs, fruits, flowers, and oils for traditional healing rituals. As central figures in their communities, *curanderas* are able to diagnose their patients based on information gathered about family relationships and the social lives of their patients, including guilt stemming from perceived sins or immoral actions. Often, patients from religious Spanish-speaking communities are more forthcoming with a healer who shares a similar cultural, religious, and linguistic background, thereby allowing *curanderas* to gather more information about the lives of their patients than medical practitioners from non-Latino communities.

Curanderas diagnose patients after a physical exam and spiritual consultation, after which treatments are commonly a mixture of prayer, psychological discovery, physical therapy, and herbal remedies. The *curandera* treats all aspects of mental, physical, and spiritual life of a patient through communal knowledge of the person's medical and psychological history, thereby focusing on the totality of a patient's needs and striving to achieve balance in the patient's life.

Curanderas often discover their ability to heal at a young age. Through a system of mentoring under an older established *curandera*, a girl or young woman apprentices to learn the healing trade. Because *curanderismo* is not a static philosophy, *curanderas* establish their own style of healing, incorporating philosophies of multiple religious and medical traditions. Some *curanderas* attend nursing school; study Eastern traditions, such as yoga and acupuncture; or

A curandera moves a chalice of burning herbs to cleanse the aura of a customer at Botanica Cristy in Santa Ana, California. The curandera uses prayer and her own touch along with herbs, fruits, flowers, and oils for traditional healing rituals. (Don Bartletti/Los Angeles Times via Getty Images)

specialize in herbal healing (*yerbera*), massage therapy (*sobadora*), or midwifery (*partera*).

A successful *curandera* can achieve prominence in her community for her ability to cure patients through natural alternative means and by performing spiritual cleansings, or *limpias*. If a *curandera* cannot diagnose natural causes for ailments in a patient, then she will try to treat supernatural causes. This belief in “magic” is central to *curanderismo*, and diagnoses range from sins a patient may have committed to the work of black magic by a witch (*bruja*). In this way, the *curandera* is believed to be a practitioner of white magic, and as God’s vessel, she works on the side of good. She acts as a bridge or translator between the patient and the voice of God. As such, a patient is expected to trust in the diagnosis of the *curandera* and actively participate in the treatment through healing rituals that involve atoning for sins and carrying out

acts of forgiveness, sacrifice, and self-discipline. While skeptics focus on this magical aspect of healing as a way of undermining faith healers, it should be noted that *curanderas* often view their healing as complementary to traditional medicine, not exclusive from it. By focusing on overlapping treatments that appeal to the cultural sensibilities of their patients, *curanderas* are able to treat their clientele with a variety of therapies.

Curanderismo is a cultural aspect of Latino communities largely unknown to majority American culture. Eurocentric representations of *curanderas* often trivialize the spiritual healing philosophy by focusing on the superstitious elements or depicting *curanderas* as greedy folk healers preying on desperate members of an ignorant community. The fact that *curanderas* are women does little to enhance their cultural power. Nonetheless, the majority of *curanderas* spend most

of their lives studying their craft and are powerful members of their communities.

Dark Matter Science

Dark matter science arose because of observations of the universe made in the 1930s with light telescope technology. Dark matter, an invisible matter, was detected by the effects (gravitational force) it had on visible material. Although some astronomers initially resisted the idea of dark matter, later observations made during the telescope technology revolution of the 1970s confirmed its existence. However, further investigations were needed to identify its nature. Although the answer to this question remained elusive, scientists seriously considered many theories as new observations of the universe revealed more of its dynamics. With the use of the Hubble Telescope in the 1990s, scientists concluded that dark matter alone was not sufficient to explain the behavior of the universe. They theorized that dark energy (another unknown entity) interacted with dark matter and the visible universe. However, due to the vastness and complexity of the universe, new discoveries often led to new mysteries. Perhaps these mysteries can be solved (or better understood) with future telescope technological innovations.

During the early 1930s, Dutch astronomer Jan Oort (1900–1992) and Swiss astronomer Fritz Zwicky (1898–1974) discovered that most of the mass in the universe did not generate light and was “hidden from view.” In 1932, Oort studied the motion of stars in the Milky Way galaxy. He observed that stars moved at high velocities around the center of the galaxy, but they did not break away from it. Scientists believed that all objects with mass generated gravitational pull, and this pull kept the galaxy together. Greater mass meant greater pull. The opposite was equally true. However, Oort calculated that the mass required to keep the galaxy intact could not be accounted for by its visible matter. The next year, Zwicky studied the motion of galaxies within the Coma cluster (which contains more than 1,000 identified galaxies). He concluded that the cluster should have spun apart billions of years ago, because its visible mass could not explain how these bodies were held in their respective orbits. Oort called the invisible mass, “hidden matter.” Zwicky called it “dark matter.”

In 1940, American astronomer Horace Badcock (1912–2003) studied the Andromeda galaxy (the Milky Way’s closest neighbor) and confirmed the dark matter phenomenon. However, some scientists denied these findings, and they speculated on other possible explanations. For example, perhaps other gravity-producing objects were, in fact, present and emitting light but were obscured from the light telescopes of that time due to interstellar dust clouds. A scientific revolution in telescope technology, however, settled the debate during the 1970s. Digital-imaging intensifiers made it possible for astronomers to confirm the existence of dark matter. Later, other new technologies allowed astronomers to make observations across several portions of the light spectrum (including radio, infrared, ultraviolet, and x-ray). These technological developments allowed scientists to rule out dust cloud obstructions. In fact, x-ray telescope technology allowed astronomers to confirm that even dust clouds were held together by some unknown gravitational pull.

By the 1990s, scientists had reached a consensus over the existence of dark matter, and research included investigations into its nature. There were several leading theories. According to the massive compact halo objects (MACHOs) theory, the unaccounted-for matter was

composed of many commonly known objects that did not shine. For example, some objects could be too small to reflect light far enough to be seen from Earth. Some larger objects, like planets, may be too far from stars to reflect light. Even the largest objects, like black holes and brown dwarfs (substellar objects that never ignite fusion reactions), may be present but unseen. However, according to the weakly interacting massive particles (WIMPs) theory, unseen matter was not composed of “normal” (or commonly known) objects. This theory referred to “exotic” forms of matter that had not yet been directly observed. Instead, dark matter was only detectable by the way it interacted with visible objects. Although both theories were popular in dark matter science, some scientists found the MACHOs theory problematic. First, few small objects had been found after more than a century of searching, which had led scientists to believe that insufficient small objects existed to account for the massive gravitational properties of dark matter. Second, during the Big Bang (the most widely accepted theory regarding the origin and initial evolution of the universe), the universe was very hot, and the majority of small objects would have been fused together to produce heavier ones. For these and other reasons, some scientists preferred the WIMPs theory.

During the 1990s, astronomers gained access to Hubble, the first large space telescope, which orbited Earth. Over the years, Hubble produced high-quality, never-before-seen images of the universe. Through the use of the technologically advanced equipment, scientists found that the universe was expanding at a tremendous rate of speed. The revelation seemed to be at odds with the accepted properties of dark matter, which was believed to keep galaxies and the entire universe intact. After the discovery of universe expansion, scientists were forced to reconcile their understanding of the properties of dark matter with those of dark energy, a new, unknown force. Dark matter, then, was described as an unknown extragravitational force that held galaxies together (like glue) as they spun at great speeds, while at the same time, dark energy pushed each intact galaxy outward from the center point of the Big Bang (like dots painted on the surface of an inflating balloon).

Dark energy was an even greater mystery than dark matter. For one thing, known physical laws dictated that universe expansion should have been slowing

down over time to a stop, and then the material of the universe should contract back to the point where the Big Bang originated (like the way a ball that is thrown in the air stops and then returns to its point of origin). However, the universe was not only defying this law of gravity, but its expansion appeared to be gaining speed. Scientists theorized that there might not be sufficient dark matter in the universe to halt its expansion, but they could not explain why expansion was accelerating. If acceleration continued, which seemed to be the case based on observations and calculations, the ultimate fate of the universe was known. Accelerated expansion would eventually disperse all galaxies beyond Earth’s light horizon, leaving the Milky Way galaxy surrounded by only the cold darkness of space.

By the 2000s, new technologies enabled scientists to confirm that dark matter did not pervade space uniformly or independently of other visible structures. Instead, its presence was concentrated in and around galaxies. By 2001, scientists had detected supermassive black holes in the center of some galaxies. Further observations in 2004 with the Very Long Baseline Array (VLBA), which was made up of 10 radio telescopes located across the United States, confirmed the presence of a large black hole (about the size of Earth’s orbit around the sun) at the center of the Milky Way. The discoveries led some scientists to believe that black holes may have supplied some (but not all) of the gravitational pull needed to keep galaxies together. Another theory centered around neutrinos (invisible subatomic particles) that scientists believed existed in great numbers in the universe. In the late 1990s, they discovered that neutrinos had mass. Consequently, some physicists theorized that the enormous number of neutrinos in the universe might account for the unexplained gravity. However, in 2002, new calculations showed that the collective mass of all neutrinos could only account for a fifth of the dark matter in the universe. After further study, scientists theorized on the makeup of the universe: 5 percent ordinary matter, 23 percent dark matter, and 72 percent dark energy. In other words, only 5 percent of the entire universe was visible to Earth and was composed of recognizable objects. The rest (95 percent) was a mystery.

Finally, in recent years, some scientists have been fascinated with how dark matter and dark energy seem

to be interchangeable. Dark matter pulls material together while dark energy pushes material away (like a magnet that can pull material toward it but also repel another magnet).

Without a doubt, new telescope technologies have revealed new aspects of the universe, but the revelations have often led to deeper mysteries. Perhaps another scientific revolution in observation technology (like the one that occurred in the 1970s) may be necessary to reach another breakthrough in dark matter science.

Dolby Laboratories

Based in San Francisco, California, Dolby Laboratories develops audio and visual technologies for use by industries such as film, video games, and music. Today, Dolby Labs is known for its work with surround sound, which is played from all directions instead of a single one. The company’s Dolby Digital product is an audio compression technique that brought surround sound to cinemas and later to home theaters, speaker systems, and other setups. Dolby Digital would later be adopted as part of the standards for DVD, Blu-ray, and broadcast systems, and even for video games and their associated systems.

Dolby Laboratories was founded in London, England on May 18, 1965, by Ray Dolby (1919–2013). It

moved to San Francisco in 1976. The company’s first products involved noise reduction systems such as the Dolby A, which was intended for professional recording studios. Studios welcomed Dolby A, as many of them were transitioning to multitrack recording in hopes of reducing loss of sound detail and depth. Dolby A would become commonplace among studios after multitrack recording became the standard.

Their focus on noise reduction systems meant that Dolby technologies were eventually used to improve audio quality in films. One of the first films to utilize its technologies was *A Clockwork Orange* (1971). Dolby Laboratories also developed a stereo sound system called Dolby Stereo, which was first used in the film *Lisztomania* (1975). Though stereo sound was not a new concept at the time, mono sound was still the standard: most recordings only utilized one channel of sound. Stereo sound allowed for more channels, but it was adopted widely by cinemas only after Dolby Stereo was used in the recording of the megahit film *Star Wars* (1977).

Dolby Stereo was then followed by Dolby Stereo Digital, later rebranded to Dolby Digital. This surround sound system was first used in *Batman Returns* (1992) and became popular in both the cinema and home after it was adopted as part of the standards for DVD. Dolby Laboratories followed it with Dolby Surround 7.1 and Dolby Atmos. The former was used first in *Toy Story 3* (2010) and the latter in *Brave* (2012). Today, these formats are now slowly being adopted for use in home theaters. Dolby Laboratories released a projection system called Dolby Vision in 2014 and followed it with the introduction of a new cinema format, Dolby Cinema.

Drones

Drones are also known by the moniker “unmanned aerial vehicles,” which points out the basic concept behind them. These tools do not require a person on board to serve as pilot and, as such, they can strike targets at a distance. Modern drones use computer inputs to achieve their targets and strike zones.

The first testing and construction of the drones in a military capacity was around 1916, during World War I, though the concept had been around for a long time. In 1849, the Italian military had used tactical weather balloons for bomb deployment. These particular war balloons would reach a certain height and then drop bombs. However, these “drones” were easier to deal with since they were balloons. The airplanes used during World War I were a better way to deploy aerial weapons. Trench warfare became outdated in the conflicts that came after World War I because now, an attacker can be far from those being attacked.

World War I military drones remained at the basic level of testing rather than used in combat. They were designed to work in the way torpedoes are used today in submarines, but they were not ready in time for use in that war. Reginald Denny is credited with creating a more modern and much more accurate drone in 1935 with the prototype RP-1, which he showed to the U.S. Army. Throughout the 1930s, Denny and his group, the Radioplane Company, continued to make new models of the RP series. The RP series worked via radio control; however, the first drone that consistently worked via radio while the drone was out of visible range was created by Edward M. Sorensen.

The U.S. Army experimented with drone warfare concepts during the 1930s as well. Throughout the 1940s and 1950s, there were many attempts to increase the potential of drones. Examples include the “Firebees” from 1951 that could fly for two hours straight at heights around 60,000 feet and World War II’s British Operation Aphrodite. In it, older planes and bombers were used to launch a variation of kamikaze attack on German strongholds. The British pilots would jump out of the planes within a certain range to the target, and radio control would take over to attempt a dive-bomb. During the Vietnam War, drones called the “Lightning Bugs” were used. The reason behind the name was the quick flash of

light when their payload hit the target. They flew around 3,500 missions. Unfortunately, with the state of the economy then, it was far too expensive to use costly drones in that conflict. Although this is an example of drones not being economically feasible, in modern times, construction upgrades have reversed that issue.

Drones have now seen an immense increase in usage in desert-related conflicts. Waging war in the Middle East is already difficult, partly because there are few huge strongholds or cities to target easily, especially as many are hidden by the desert itself, or the enemy is cell based and moves underground in tunnels. The interest in more precise drones increased in reaction to the terrorist attacks of September 11, 2001, in the United States. Current drones are much smaller than those of yesteryear. Currently, the most well-known drone used by the United States is the MQ 1 Predator missile. It has over 200 that can be flown across the planet for precision strikes. In 2015, the number of kills achieved by Predator missiles was well over 3,900. The Predator uses satellite imaging and computers for targeting rather than the radio concept of older models. However, it still needs to initiate contact with a ground facility to use its talents properly.

The importance of military-based drones has been proven through the tactical information that they can provide and the strikes they are capable of from a very safe distance. Developing even precision is of the utmost importance to protect innocent civilians near strike zones so prevent them from becoming casualties of war. Restrictions can be built into drones, and constant updating of the knowledge of drones in use by other world powers is paramount for keeping countries safe from strikes.

Drones can be very useful but are much like the new nuclear weapons in their potential as tools to make other countries yield. The main function of drones is to attack at a distance while keeping one’s own military as safe as possible. Drones are now being considered for domestic use in the United States to survey situations and help the police react as needed.

Electric Car

Electric cars have a long history in the United States, as they were first used in the mid-to-late-1800s. In modern times, the need for alternatives to hydrocarbon-based fuels has increased immensely, as have the abilities of electric vehicles. Hydrocarbon fuels, also known as fossil fuels, represent a finite source on the planet, while electricity can be continually generated. Steam was another option used for cars in early days, but it proved less practical than electricity or fossil fuels.

One of the first electric vehicles was built in 1859 in France, crafted by Gaston Plante. It used a lead-acid battery to store electrical energy. The design was refined by Camille Alphonse Faure around 1881, leading to better capacity in the battery and therefore longer usage of the car. In 1890 in the United States, William Morrison, a chemist, designed the first electric car, a six-passenger vehicle capable of a top speed of 14 miles per hour.

Shortly afterward, electric cars enjoyed a relative period of success, beating many speed records, and the public seemed interested. By the end of the 1800s, electric taxis became the norm in London, which helped the economy and British tourism goals. While gasoline-powered cars debuted around the same time, they had detractors. Drivers complained about the strength required to change gears and of the inconvenience of starting the cars with a hand crank. Gasoline-powered engines were loud, and the exhaust caused coughing and dirty clothing.

Thomas Edison believed in the superiority of electric technology and developed a more powerful electric vehicle battery. He partnered with Henry Ford to design a low-cost electric car, but Ford continued to sell gasoline-powered cars and made more of them on his

moving assembly line and therefore, they were more affordable. In 1912, his Model T gasoline-powered car cost \$650, while an electric roadster sold for \$1,750.

Customers began to see that electric cars had their drawbacks, as they were slower and could not go far outside city limits. Electric cars declined in popularity in the 1920s, as they simply could not measure up to petroleum-powered cars, which were boosted by the newly discovered oil fields across the country. These oil reserves stole attention from the electric car, as it was easier to use gasoline than charge a battery. However, electricity was still a component in gasoline-powered cars, as they used an electric starter crafted by Charles Kettering before the 1920s. Electric cars soon fell out of the limelight.

The oil shortage in the 1960s and 1970s encouraged the U.S. government to pass the Electric and Hybrid Vehicle Research, Development, and Demonstration Act of 1976, pushing for more research into electric and hybrid vehicles. In 1971, there was an opportunity for the electric vehicle to show its worth as a manned electrical buggy became famous as the first vehicle on the surface of the moon. A fossil fuel buggy would obviously have been an issue as soon as it ran out of fuel. But this buggy generated its own energy.

However, none of these attempts garnered enough respect or buzz in the world for electric cars to challenge gasoline-powered cars. Despite the gas crisis, after the 1970s, there was a deep drop in interest in them. It wasn't until the 1990s that interest in using electric energy returned, especially with the government passing new clean air acts to help usher in an ecologically safer environment for the public to contribute to through their vehicle choices.

One of the most famous models of electric cars is one that is not fully electric but a hybrid. The Toyota Prius, introduced in Japan in 1997, was a big success on the nationwide market. Then in the new millennium, Tesla Motors, a California motor company named for Nikola Tesla, began working on all-electric cars in 2004. It brought out its first example, the Tesla Roadster, in 2008, but it stopped selling them in 2011, as a crucial part needed to construct it had run out.

The potential of electrically powered vehicles has grown as people recognize that the fossil fuels we have come to rely on have a finite life. Electrically

powered vehicles are also much cleaner in construction today and leave a cleaner ecological footprint on the roads they travel.

However, until these vehicles are cheaper and more accessible, the world will continue to rely on gasoline-fueled models.

Primary Document: Article from the energy.gov Web Site on Electric Cars (2014)

Once we run out of fossil fuels, humans will need to find a new power source for vehicles in the public sector, so we have recently returned to electricity as a possible source. This article from the energy.gov website illustrates the development of electronic cars in the United States. The concept has been around for over a hundred years.

By Rebecca Matulka

Introduced more than 100 years ago, electric cars are seeing a rise in popularity today for many of the same reasons they were first popular.

Whether it's a hybrid, plug-in hybrid or all-electric, the demand for electric drive vehicles will continue to climb as prices drop and consumers look for ways to save money at the pump. Currently more than 3 percent of new vehicle sales, electric vehicles sales could to grow to nearly 7 percent—or 6.6 million per year—worldwide by 2020, according to a report by Navigant Research.

With this growing interest in electric vehicles, we are taking a look at where this technology has been and where it's going. Travel back in time with us as we explore the history of the electric car.

THE BIRTH OF THE ELECTRIC VEHICLE

It's hard to pinpoint the invention of the electric car to one inventor or country. Instead it was a series of breakthroughs—from the battery to the electric motor—in the 1800s that led to the first electric vehicle on the road.

In the early part of the century, innovators in Hungary, the Netherlands and the United States—including

a blacksmith from Vermont—began toying with the concept of a battery-powered vehicle and created some of the first small-scale electric cars. And while Robert Anderson, a British inventor, developed the first crude electric carriage around this same time, it wasn't until the second half of the 19th century that French and English inventors built some of the first practical electric cars.

Here in the U.S., the first successful electric car made its debut around 1890 thanks to William Morrison, a chemist who lived in Des Moines, Iowa. His six-passenger vehicle capable of a top speed of 14 miles per hour was little more than an electrified wagon, but it helped spark interest in electric vehicles.

Over the next few years, electric vehicles from different automakers began popping up across the U.S. New York City even had a fleet of more than 60 electric taxis. By 1900, electric cars were at their heyday, accounting for around a third of all vehicles on the road. During the next 10 years, they continued to show strong sales.

THE EARLY RISE AND FALL OF THE ELECTRIC CAR

To understand the popularity of electric vehicles circa 1900, it is also important to understand the development of the personal vehicle and the other options available. At the turn of the 20th century, the horse was still the primary mode of transportation. But as Americans became more prosperous, they turned to the newly invented motor vehicle—available in steam, gasoline or electric versions—to get around.

Steam was a tried and true energy source, having proved reliable for powering factories and trains.

Some of the first self-propelled vehicles in the late 1700s relied on steam; yet it took until the 1870s for the technology to take hold in cars. Part of this is because steam wasn't very practical for personal vehicles. Steam vehicles required long startup times—sometimes up to 45 minutes in the cold—and would need to be refilled with water, limiting their range.

As electric vehicles came onto the market, so did a new type of vehicle—the gasoline-powered car—thanks to improvements to the internal combustion engine in the 1800s. While gasoline cars had promise, they weren't without their faults. They required a lot of manual effort to drive—changing gears was no easy task and they needed to be started with a hand crank, making them difficult for some to operate. They were also noisy, and their exhaust was unpleasant.

Electric cars didn't have any of the issues associated with steam or gasoline. They were quiet, easy to drive and didn't emit a smelly pollutant like the other cars of the time. Electric cars quickly became popular with urban residents—especially women. They were perfect for short trips around the city, and poor road conditions outside cities meant few cars of any type could venture farther. As more people gained access to electricity in the 1910s, it became easier to charge electric cars, adding to their popularity with all walks of life (including some of the “best known and prominent makers of gasoline cars” as a 1911 New York Times article pointed out).

Many innovators at the time took note of the electric vehicle's high demand, exploring ways to improve the technology. For example, Ferdinand Porsche, founder of the sports car company by the same name, developed an electric car called the P1 in 1898. Around the same time, he created the world's first hybrid electric car—a vehicle that is powered by electricity and a gas engine. Thomas Edison, one of the world's most prolific inventors, thought electric vehicles were the superior technology and worked to build a better electric vehicle battery. Even Henry Ford, who was friends with Edison, partnered with Edison to explore options for a low-cost electric car in 1914, according to *Wired*.

Yet, it was Henry Ford's mass-produced Model T that dealt a blow to the electric car. Introduced in 1908, the Model T made gasoline-powered cars widely available and affordable. By 1912, the gasoline car cost only \$650, while an electric roadster sold for \$1,750. That same year, Charles Kettering

introduced the electric starter, eliminating the need for the hand crank and giving rise to more gasoline-powered vehicle sales.

Other developments also contributed to the decline of the electric vehicle. By the 1920s, the U.S. had a better system of roads connecting cities, and Americans wanted to get out and explore. With the discovery of Texas crude oil, gas became cheap and readily available for rural Americans, and filling stations began popping up across the country. In comparison, very few Americans outside of cities had electricity at that time. In the end, electric vehicles all but disappeared by 1935.

GAS SHORTAGES SPARK INTEREST IN ELECTRIC VEHICLES

Over the next 30 years or so, electric vehicles entered a sort of dark ages with little advancement in the technology. Cheap, abundant gasoline and continued improvement in the internal combustion engine hampered demand for alternative fuel vehicles.

Fast forward to the late 1960s and early 1970s. Soaring oil prices and gasoline shortages—peaking with the 1973 Arab Oil Embargo—created a growing interest in lowering the U.S.'s dependence on foreign oil and finding homegrown sources of fuel. Congress took note and passed the Electric and Hybrid Vehicle Research, Development, and Demonstration Act of 1976, authorizing the Energy Department to support research and development in electric and hybrid vehicles.

Around this same time, many big and small automakers began exploring options for alternative fuel vehicles, including electric cars. For example, General Motors developed a prototype for an urban electric car that it displayed at the Environmental Protection Agency's First Symposium on Low Pollution Power Systems Development in 1973, and the American Motor Company produced electric delivery jeeps that the United States Postal Service used in a 1975 test program. Even NASA helped raise the profile of the electric vehicle when its electric Lunar rover became the first manned vehicle to drive on the moon in 1971.

Yet, the vehicles developed and produced in the 1970s still suffered from drawbacks compared to gasoline-powered cars. Electric vehicles during this time had limited performance—usually topping at speeds of 45 miles per hour—and their typical range was limited to 40 miles before needing to be recharged.

ENVIRONMENTAL CONCERN DRIVES ELECTRIC VEHICLES FORWARD

Fast forward again—this time to the 1990s. In the 20 years since the long gas lines of the 1970s, interest in electric vehicles had mostly died down. But new federal and state regulations begin to change things. The passage of the 1990 Clean Air Act Amendment and the 1992 Energy Policy Act—plus new transportation emissions regulations issued by the California Air Resources Board—helped create a renewed interest in electric vehicles in the U.S.

During this time, automakers began modifying some of their popular vehicle models into electric vehicles. This meant that electric vehicles now achieved speeds and performance much closer to gasoline-powered vehicles, and many of them had a range of 60 miles.

One of the most well-known electric cars during this time was GM's EV1, a car that was heavily featured in the 2006 documentary *Who Killed the Electric Car?* Instead of modifying an existing vehicle, GM designed and developed the EV1 from the ground up. With a range of 80 miles and the ability to accelerate from 0 to 50 miles per hour in just seven seconds, the EV1 quickly gained a cult following. But because of high production costs, the EV1 was never commercially viable, and GM discontinued it in 2001.

With a booming economy, a growing middle class and low gas prices in the late 1990s, many consumers didn't worry about fuel-efficient vehicles. Even though there wasn't much public attention to electric vehicles at this time, behind the scenes, scientists and engineers—supported by the Energy Department—were working to improve electric vehicle technology, including batteries.

A NEW BEGINNING FOR ELECTRIC CARS

While all the starts and stops of the electric vehicle industry in the second half of the 20th century helped show the world the promise of the technology, the true revival of the electric vehicle didn't happen until around the start of the 21st century. Depending on whom you ask, it was one of two events that sparked the interest we see today in electric vehicles.

The first turning point many have suggested was the introduction of the Toyota Prius. Released in

Japan in 1997, the Prius became the world's first mass-produced hybrid electric vehicle. In 2000, the Prius was released worldwide, and it became an instant success with celebrities, helping to raise the profile of the car. To make the Prius a reality, Toyota used a nickel metal hydride battery—a technology that was supported by the Energy Department's research. Since then, rising gasoline prices and growing concern about carbon pollution have helped make the Prius the bestselling hybrid worldwide during the past decade.

(Historical footnote: Before the Prius could be introduced in the U.S., Honda released the Insight hybrid in 1999, making it the first hybrid sold in the U.S. since the early 1900s.)

The other event that helped reshape electric vehicles was the announcement in 2006 that a small Silicon Valley startup, Tesla Motors, would start producing a luxury electric sports car that could go more than 200 miles on a single charge. In 2010, Tesla received a \$465 million loan from the Department of Energy's Loan Programs Office—a loan that Tesla repaid a full nine years early—to establish a manufacturing facility in California. In the short time since then, Tesla has won wide acclaim for its cars and has become the largest auto industry employer in California.

Tesla's announcement and subsequent success spurred many big automakers to accelerate work on their own electric vehicles. In late 2010, the Chevy Volt and the Nissan LEAF were released in the U.S. market. The first commercially available plug-in hybrid, the Volt has a gasoline engine that supplements its electric drive once the battery is depleted, allowing consumers to drive on electric for most trips and gasoline to extend the vehicle's range. In comparison, the LEAF is an all-electric vehicle (often called a battery-electric vehicle, an electric vehicle or just an EV for short), meaning it is only powered by an electric motor.

Over the next few years, other automakers began rolling out electric vehicles in the U.S.; yet, consumers were still faced with one of the early problems of the electric vehicle—where to charge their vehicles on the go. Through the Recovery Act, the Energy Department invested more than \$115 million to help build a nation-wide charging infrastructure,

installing more than 18,000 residential, commercial and public chargers across the country. Automakers and other private businesses also installed their own chargers at key locations in the U.S., bringing today's total of public electric vehicle chargers to more than 8,000 different locations with more than 20,000 charging outlets.

At the same time, new battery technology—supported by the Energy Department's Vehicle Technologies Office—began hitting the market, helping to improve a plug-in electric vehicle's range. In addition to the battery technology in nearly all of the first generation hybrids, the Department's research also helped develop the lithium-ion battery technology used in the Volt. More recently, the Department's investment in battery research and development has helped cut electric vehicle battery costs by 50 percent in the last four years, while simultaneously improving the vehicle batteries' performance (meaning their power, energy and durability). This in turn has helped lower the costs of electric vehicles, making them more affordable for consumers.

Consumers now have more choices than ever when it comes to buying an electric vehicle. Today, there are 23 plug-in electric and 36 hybrid models available in a variety of sizes—from the two-passenger Smart ED to the midsize Ford C-Max Energi to the BMW i3 luxury SUV. As gasoline prices continue to rise and the prices on electric vehicles continue to drop, electric vehicles are gaining in popularity—with more than 234,000 plug-in electric vehicles and 3.3 million hybrids on the road in the U.S. today.

THE FUTURE OF ELECTRIC CARS

It's hard to tell where the future will take electric vehicles, but it's clear they hold a lot of potential for creating a more sustainable future. If we transitioned all the light-duty vehicles in the U.S. to hybrids or plug-in electric vehicles using our current technology mix, we could reduce our dependence on foreign oil by 30-60 percent, while lowering the carbon pollution from the transportation sector by as much as 20 percent.

To help reach these emissions savings, in 2012 President Obama launched the EV Everywhere Grand Challenge—an Energy Department initiative that brings together America's best and brightest

scientists, engineers and businesses to make plug-in electric vehicles more as affordable as today's gasoline-powered vehicles by 2022. On the battery front, the Department's Joint Center for Energy Storage Research at Argonne National Laboratory is working to overcome the biggest scientific and technical barriers that prevent large-scale improvements of batteries.

And the Department's Advanced Research Projects Agency-Energy (ARPA-E) is advancing game-changing technologies that could alter how we think of electric vehicles. From investing in new types of batteries that could go further on a single charge to cost-effective alternatives to materials critical to electric motors, ARPA-E's projects could transform electric vehicles.

In the end, only time will tell what road electric vehicles will take in the future.

WHAT'S THE DIFFERENCE?

A hybrid electric vehicle (or HEV for short) is a vehicle without the capacity to plug in but has an electric drive system and battery. Its driving energy comes only from liquid fuel. Learn about the history of the hybrid—from the world's first one to the world's bestselling one.

A plug-in hybrid electric vehicle (also called a PHEV) is a vehicle with plug-in capability, and it can use energy for driving from either its battery or liquid fuel. Read about the first commercially available plug-in hybrid.

An all-electric vehicle (often called a battery-electric vehicle, an electric vehicle, or an EV or AEV for short) is a vehicle that gets its energy for driving entirely from its battery and it must be plugged in to be recharged. Explore the evolution of the electric vehicle, covering everything from its early popularity to the middle ages to its revival today.

A plug-in electric vehicle (or PEV) is any vehicle that can be plugged in (either a plug-in hybrid or an all-electric vehicle). Learn how plug-in electric vehicles could help us create a more sustainable future.

Enders, John Franklin (1897–1985)

John Franklin Enders was a Nobel Prize virologist whose pioneering discoveries in the field of virology granted him the title of “the Father of Modern Vaccines.” Together with his colleagues Thomas Weller and Frederick Robbins, he discovered new tissue culture techniques to grow viruses that later led to the development of poliomyelitis and measles vaccines. His groundbreaking discoveries have saved over 100 million lives.

Enders was born in West Hartford, Connecticut, on February 10, 1897. Son of a banker in Hartford, he showed no interest in science during his youth. After attending Yale University for just two years, Enders joined the U.S. Air Force in 1917, becoming a pilot with the rank of ensign. When the First World War was over, he returned to Yale, where he was awarded his AB in English in 1919. He tried to follow in his father’s footsteps, working in real estate for two years, but he quickly found this career to be rather dull. In the next four years, he enrolled in graduate school at Harvard to study English literature as well as Germanic and Celtic languages, hoping to become an English teacher. However, he was not happy about this choice either, and in 1927, he left his studies to enter as a candidate for the PhD degree in bacteriology and immunology after being introduced to his new mentor, Dr. Hans Zinsser. After he earned his PhD in 1930, Enders joined the bacteriology faculty at Harvard Medical School, where he remained until the end of his career.

In 1941, Enders and his colleagues Cohen, Stokes, Kane, and others, started a study of the virus of mumps that demonstrated the immunizing effects of inactivated viruses. In 1946, he established a laboratory at Children’s Hospital in Boston, where he led several studies on the polio virus. In 1949, together with Thomas Huckle Weller and Frederick Chapman Robbins, Enders came up with a breakthrough discovery that revolutionized the fight against the ongoing poliomyelitis epidemic that ravaged the United States. Before this research, scientists who wanted to grow the polio virus were forced to inoculate it in live monkeys and later retrieve minuscule quantities from their corpses during autopsies. The newly discovered Enders technique allowed researchers to culture the virus in test tubes, paving the way for the mass production of the Jonas Salk vaccine and Albert Sabin’s killed-virus and live-virus vaccines. This

technique quickly became an invaluable tool for all virologists across the world by reducing the cost and time required to study many other viruses as well. In 1954, Enders, Weller, and Robbins received the Nobel Prize in Physiology or Medicine for their work on culturing the polio virus in various types of tissue.

After being appointed professor at Harvard University and chief of the Research Division of Infectious Diseases at Children’s Hospital, in 1953, Enders formed a new team with Thomas Peebles to start researching the measles virus. Although measles did not kill patients who contracted it in Western countries outright, it was an extremely contagious disease that affected 9 out of 10 children. More than 6 million children who caught it died every year in less developed regions of the world, nearly twice as many as those who died from polio. After Enders’s team had isolated the virus, they started developing an attenuated live-virus measles vaccine. In 1960, he handed the vaccine off to Dr. Maurice Hilleman, who was the head of the research department at the pharmaceutical company Merck, Sharp, and Dohme. Hilleman perfected and distributed it in 1963.

Enders was a member of the American Academy of Arts and Sciences, the National Academy of Sciences, and the American Philosophical Society. During his career, he received several prizes, including the Albert Lasker Basic Medical Research Award (1954), the Presidential Medal of Freedom (1963), and the Robert Koch Prize (1963). He was also awarded honorary doctoral degrees from 13 universities.

Enders officially retired in 1967 at the age of 70. However, he kept teaching and researching up until 1976, as he continued the studies on virus-host relationships and viral oncogenesis he had started in 1959. He died on September 8, 1985, in his home in Waterford, Connecticut, at the age of 88.

Engelbart, Douglas (1925–2013)

The grandson of pioneers in the West, Douglas Engelbart was known as an engineer and inventor. Engelbart, known as “Doug” to many, also served in the military for two years, but he is mainly known as the creator of the computer mouse. Also, he had a vision all his life for “augmenting the human intellect” through working with interactive computers and helping intellectual workers to become more capable.

Engelbart was born on January 30, 1925, in Portland, Oregon. He was the son of Carl and Gladys Engelbart. He had two other siblings: an older sister named Dorianne Engelbart Vadnais and a younger brother named David Engelbart. He attended Franklin High School and then Oregon State University. There, he studied electrical engineering. In 1944, he enlisted in the navy during World War II and served two years as an electronic and radar technician stationed in the Philippines.

In 1948, he earned a bachelor’s degree and was given a position at California’s Ames Research Center. This was a government laboratory overseen by the National Advisory Committee for Aeronautics. He spent a number of years there before earning his PhD in electrical engineering at the University of California, Berkeley. In 1957, he took a research position at Stanford Research Institute.

In 1961, Engelbart first came up with the idea of the computer mouse as a way to make interactive computing easier. He built the first prototype in 1964, carving it from wood. It had wheels on the bottom so the computer could track the rotation of the mouse and move the cursor displayed on the computer screen. Finally, there was a button on the right corner, used for clicking items on the screen.

Over the years, the dimensions and materials of the computer mouse gradually changed, but its purpose has remained the same. Douglas Engelbart developed many computer-related inventions, including interactive computing and the keyset. After many years of success, Douglas Engelbart died July 2, 2013 in Atherton, California.

ENIAC and the “ENIAC Girls”

ENIAC, or “Electrical Numerical Integrator and Computer,” was the first electronic general-purpose computer. It was used to calculate artillery firing tables for the U.S. Army’s Ballistic Research Laboratory and to study the feasibility of thermonuclear weapons. It was primarily operated by a group of women known as the “ENIAC Girls.”

Financed by the U.S. Army, Ordnance Corps, Research and Development Command at a cost of \$487,000, ENIAC was the first electronic general-purpose computer in the world. The computer was designed by John Mauchly and J. Presper Eckert with the assistance of Robert F. Shaw (function tables), Jeffrey Chuan Chu (divider/square-rooter), Thomas Kite Sharpless (master programmer), Frank Mural (master programmer), Arthur Burks (multiplier), Harry Huskey (reader/printer), and Jack Davis (accumulators). ENIAC was completed in secret in 1943 at the University of Pennsylvania’s Moore School of Electrical Engineering, under the code name “Project PX,” and formally dedicated on February 15, 1946.

ENIAC was a modulator computer, composed of individual panels to perform different functions, at a speed one thousand times faster than previous electro-mechanical machines. Twenty of its panels were accumulators, which could add, subtract, and hold a 10-digit

decimal number in memory. Punch cards from an IBM card reader were used as external memory. ENIAC could also be programmed to perform complex sequences of operations, including loops, branches, and subroutines. The task of mapping a problem onto the machine to run the operations was complex and usually took weeks of figuring out the program on paper, manipulating switches and cables, verification, and debugging.

To accomplish this task, the army hired a group of female programmers, known as the “ENIAC Girls,” drafted from the Moore School of Electrical Engineering at the University of Pennsylvania. The original group included Kay McNulty, Betty Jennings, Betty Snyder, Marlyn Wescoff, Fran Bilas, and Ruth Lichterman. They were tasked with determining how to input programs into the computer and develop an understanding of ENIAC’s inner workings by crawling inside the machine to fix problems and make observations. None of the ENIAC Girls received public recognition for their work, which was classified as a clerical task. Some have since been recognized for their contributions to computing, including their induction into the Women in Technology International Hall of Fame in 1997.

Following the original group of six, over one hundred scientists were recruited to continue work on ENIAC, including several women. Their work played a key role in several computing developments, including the first computations for the hydrogen bomb and the popularization of the Monte Carlo method, which calculated the distance that neutrons would likely travel through various materials. ENIAC was shut down on November 9, 1946, for a refurbishment and a memory upgrade. It was transferred to the Aberdeen Proving Ground in Maryland in 1947, where it remained in continuous operation until 11:45 p.m. on October 2, 1955. Unlike other computers of its time, ENIAC was widely discussed in the press. Its one-of-a-kind design formed the basis for later computers, and today, several parts of ENIAC are on display at museums in the United States, England, and Germany.

Fortran

Fortran, or FORTRAN, derives its name from “formula translation,” the computer language that introduced the concept of compilers. Fortran allowed software to be produced for all types of hardware and was a pivotal programming language in the electronic revolution of the late 20th century.

In the mid-20th century, software was heavily defined by the hardware it was applied to; programmers who coded for a specific hardware had to manually manage the allocation of memory and such in their code. Thus, code on one machine would not necessarily be able to function on a machine that contained different memory allocations, system details, and so on. Because of this, producing code was both inefficient and tedious for programmers.

From 1954 to 1957, a development team at International Business Machines (IBM) led by John Backus produced a software language that worked around this issue. IBM shipped the software out with the IBM 704 computer.

Fortran was the first programming language that was made to be independent from the hardware system. It featured a compiler that allowed high-level code, which resembled words and sentence-like structures. These structures were compiled into machine language composed of 0s and 1s. Through this compiler, programmers could worry less about hardware-dependent issues and focus their efforts on solving the mathematical and/or logical issues with the problem at hand. Because of this, one of the major advantages of the language was its ability to speed up the process of software development; even though the software performance was reduced by about a fifth, the compiler alone made coding five times more efficient.

Additionally, Fortran solved a number of other issues persistent in previous programming languages. Fortran became one of the first languages that could identify parenthetical operations in mathematical

statements and thus could properly translate with the correct order of operations. This made number crunching significantly easier, because the functions could now be expressed more algebraically. As such, the programming language was heavily favored in applications that required high-performance computation, such as engineering models and simulations. Furthermore, the language introduced concepts of comments in the code, a convention that improved code quality and became common coding practice.

Fortran revolutionized the software industry by improving the efficiency of both the language capabilities and the programmer. It inspired the birth of many other common programming languages, such as C, C++, and more, and is still used in computation for scientific models in fields such as fluid dynamics, physics, chemistry, and meteorology due to its ability to rapidly compute numerical calculations.

Fuller, Richard Buckminster (1895–1983)

A geodesic dome is a sphere made up of multitudes of triangles put together, almost forming small pyramids, in the shape of a sphere. This complex building structure was created by American inventor Richard Buckminster Fuller, also known as “Bucky.” The most famous of Fuller’s designs was the Biosphere located in Montreal on Saint Helen’s Island. The United States employed Fuller to design the pavilion for the 1967 World’s Fair Exposition in Montreal. The Biosphere stands 62 meters high, with a diameter of 67 meters. It is taller than a seven-story building. In 1976, the acrylic surrounding the dome caught fire during routine welding maintenance. In 1995, the Biosphere was reopened to the

public as a museum dedicated to environmental action. Closed once again in 1998 after a damaging ice storm, the Biosphere and its museum were reopened five months later.

Fuller was born on July 12, 1895, in Milton, Massachusetts. When he was young, Fuller and his family would take trips to Bear Island in Maine, and that’s how he learned how to build and repair boats. He entered Harvard College in 1913 but was soon expelled due to socializing too much and neglecting his midterms. After his expulsion, Fuller worked for a mill in Canada, where he became interested in the inner works of the mill equipment and learned how to improve it. Fuller later reapplied to Harvard and was accepted, but he was soon expelled again.

Fuller served in the U.S. Navy from 1917 to 1919. During this time, he invented a winch that could fish downed planes out of the water. Impressed by his invention, the navy nominated him for officer training at the Naval Academy, where he studied how to look at problems thoroughly. In 1926, Fuller helped his father-in-law patent his new method of strengthening concrete, which became the first of his many patents. A year later, Fuller invented a housing structure that could be quickly and easily delivered by air: the Dymaxion House. It was originally called the “4D House,” but the name was later changed by a store that advertised them. Along with the Dymaxion homes, Fuller also created Dymaxion cars, which had three wheels and great turning maneuverability. He also invented the Dymaxion Bathroom and Dymaxion Development Units, or DDUs for short, which were used during World War II to shield radar crews from harsh weather.

In 1944, the United States suffered from low housing availability. Needing housing that could be made quickly and easily, the government looked to Fuller to help end this crisis. Multitudes of people began to send in checks for Dymaxion homes, but unfortunately, Fuller could not get their production into full throttle. He felt that his design could be improved in some way, so he set out to perfect it.

In 1947, Fuller designed the building structure for which he would be most known, the geodesic dome. His design was easy to assemble, it was low cost, and it was lighter than other structures. The spherical shape of the dome allowed for more volume internally

while using the least amount of surface area, which meant less material required for manufacture. The spherical shape also allowed for easier air circulation and therefore easier heating and cooling. Fuller patented the geodesic dome in 1954. The military turned out to be Fuller's biggest client, using his dome to mask radar stations. Fuller died on July 1, 1983, in Los Angeles, but his geodesic domes are still being used all around the world.

Primary Document: Drawing of R. Buckminster Fuller's Geodesic Dome (c. 1933)

Richard Buckminster Fuller had a vision of homes that could be fabricated in a factory and easily flown in by helicopter to any location and lived in comfortably. The structure of these houses is now called the geodesic dome, but Fuller first named his odd idea the Dymaxion House. The idea of living in a dome home was not a popular one, but Fuller gained a

patent for it, and several were made for the U.S. Marine Corps. The best known of Fuller's designs is the U.S. Pavilion at the 1967 Expo in Montreal. Fuller also lived in a geodesic house with his wife, Anne, in which he designed many other domes.

Global Positioning System (GPS)

Global Positioning System (GPS) is a satellite utility owned and maintained by the U.S. Department of Defense. GPS provides military and civilians with timing, positioning, and navigation services. Roger L. Easton of the Naval Research Laboratory, Ivan A. Getting of the Aerospace Corporation, and Bradford Parkinson of the Applied Physics Laboratory are credited with its invention. The U.S. Air Force launched the first GPS satellite, the Navigation Satellite with Timing and Ranging (NAVSTAR), on February 22, 1978.

The GPS system consists of three segments: the space segment, the control segment, and the user segment. The space segment is made up of a constellation of at least 24 NAVSTARs precisely orbiting the earth twice in the span of 24 hours. The satellites are set in a way that allows at least four of them to be in direct line of sight from anywhere on earth. Each satellite has an extremely accurate atomic clock powered by quantum physics. The satellites each transmit a unique signal (with the exact time it is sent) called Pseudo Random Code (PRC) so that they don't interfere with each other. Each NAVSTAR weighs 2,200 pounds and travels 8,640 miles per hour.

The GPS receiver (the user segment) receives these signals. The amount of time it takes the receiver to get the signals determines the distance between the satellites and the receiving device (distance = velocity x time), providing exact location (using relative distance to satellites), precise maps, and navigation. In 1989, Magellan Systems Corporation, based in San Dimas, California, was the first company in the world to introduce a portable GPS receiver for civilians called the NAV 100. This led to a boom in the GPS market. Finally, the control segment consists of a worldwide control station that makes sure that the satellites are in proper position.

The U.S. Air Force develops, maintains, and operates the space and control segments of GPS. The system became available to civilians in 1983 after a Korean

passenger jet unintentionally entered prohibited Soviet airspace and was shot down by a Soviet aircraft, resulting in the death of the passengers. The U.S. government acknowledged that this accident could have been avoided if GPS technology had been available. President Ronald Reagan announced that GPS technology would be available to civilians, and it is now freely available to anyone on a global scale. The military services are available to U.S. government and allied forces. Military and civilian access to GPS is different; the civilian version of GPS is much less complicated and lower in accuracy. GPS technology is constantly updated. It provides 24-hour data that is extremely accurate in providing three-dimensional location information, including longitude, latitude, and altitude. It also provides the user with accurate speed and time.

GPS was originally called Navstar GPS. It was a project by the U.S. Department of Defense launched in 1973 for U.S. military use but did not become fully operational until 1995. GPS is not the only system of its kind, although it is the prominent one. Other systems are in use or under development by other countries, mainly because it is U.S. property, and the American government and military have the power to deny access to any opposing forces. This happened to the Indian military in 1999 during the Kargil War.

Some of the other current GPS systems operating around the world are Russia's Global Navigation Satellite System (GLONASS), Europe's Union Galileo Positioning System, China's BeiDou Navigation Satellite System, India's NAVIC, and Japan's Quasi-Zenith Satellite System. GPS was created using information from previous systems that were less functional and with engineering design studies that took place in the 1960s. The system was originally designed with references to similar radio navigation systems used by the British Royal Navy during World War II such as the loran and Decca Navigator.

GPS is a technology that once began as a military weapon and has become part of everyday civilian life. GPS technology has been a major influence on the rise of many different markets and has become a market of its own. The availability of GPS to the public has revolutionized life. Today, civilian GPS receivers, most commonly found in smartphones, are used to navigate anywhere, to check traffic in real time, and to explore

places near or far away. As GPS technology rapidly continues to be updated, we can expect to continue incorporating receivers into new technological gadgets.

Goeppert-Mayer, Maria (1906–1972)

In 1963, Maria Goeppert-Mayer won the Nobel Prize in Physics for describing the nuclear shell model for the atomic nucleus. She was the second woman to win the award. Goeppert also developed the two-photon absorption theory and contributed to the Manhattan Project.

German theoretical physicist Maria Goeppert-Mayer gained her PhD in Germany in 1930. She then moved to the United States with her husband, where she worked on the Manhattan Project, which produced the first atomic bomb. Maria Goeppert was born on June 28, 1906, in Kattowitz, Prussia (now Katowice, Poland).

Physicist Dr. Maria Goeppert-Mayer, who became the second woman in history to win a Nobel Prize, holds the Nobel medal she won in 1963 for her work in atomic physics. (Bettmann/Getty Images)

In 1910, her family moved to Göttingen, Germany, so her father could teach pediatric medicine at the university. Because of her father's status, as a child, Goeppert was able to enroll in some of the best schools. She passed the entry exam for Göttingen University in 1924.

Originally, Goeppert entered the university as a mathematics major, working with Amalie "Emmy" Noether, a noted mathematician. After witnessing a lecture by Max Born on the early discoveries of quantum mechanics, Goeppert became inspired to study physics. Later, Born would oversee her doctoral dissertation on two-photon absorption. Goeppert's thesis was far ahead of its time. Although her photon theory could not be tested until lasers were invented, Goeppert's thesis was considered groundbreaking work.

In the late 1920s, Goeppert met Joseph Edward Mayer, an American physics student studying at Göttingen. They married in 1930. After graduating that same year, Mayer was hired at Johns Hopkins University in

Baltimore, Maryland. Goeppert-Mayer went with him to America. The Great Depression and her gender limited her ability to work. Johns Hopkins University had strong rules against hiring spouses, but the Physics Department allowed her to use its laboratories for free. Unpaid, she worked with graduate students on their dissertations.

In 1941, Goeppert-Mayer found her first job teaching physics at Sarah Lawrence College in New York City. Through connections she had made over the years, she was offered a second job with Columbia University's Substitute Alloy Material (SAM) Project. The SAM Project was a cover for the Manhattan Project, and Goeppert-Mayer's assignment was to help refine uranium ore for its destructive isotopes and to study its thermodynamic properties.

In 1946, Goeppert-Mayer and Mayer moved to Chicago. Goeppert-Mayer worked for the Atomic Energy Commission at the Argonne National Laboratory. She also volunteered her time at the University of Chicago, where Mayer worked as well. There, Goeppert-Mayer became interested in the origin of the elements. After reading through decades of research and studies by other scientists, she noticed that several numbers kept reoccurring—2, 8, 20, 28, 50, 82, and 126. They were dubbed “magic numbers” by Eugene Wigner a few years before and were often associated with the numbers of protons, electrons, and neutrons inside an atom.

Goeppert-Mayer worked on developing a mathematical model of why these numbers were so magical and stable. She developed the nuclear shell model to explain why some numbers were more stable than others. The nucleus, according to her, was a series of “shells” (layers) where protons and neutrons coupled up. As these particles bind to each other, they orbit clockwise within the nucleus while spinning in a counterclockwise direction. Finally, the nucleus can hold twice as many particles as long as the second set of proton/neutron couplings orbits counterclockwise while spinning clockwise. Goeppert-Mayer made the analogy that her model was a ballroom dance, with particles dancing with other particles in an intricate ballet.

When Goeppert-Mayer presented her findings to the science journal *Physical Review*, the editor informed her that the journal had just received a nearly identical paper on the topic. A team of German scientists had

independently reached the same conclusion on the nuclear shell model. Goeppert-Mayer contacted the team leader, J. Hans D. Jensen, to discuss their ideas. The two published their book, *Elementary Theory of Nuclear Shell Structure*, in 1950. In 1963, Goeppert-Mayer, Jensen, and Wigner received the Nobel Prize in Physics for their work. Goeppert-Mayer was the only woman besides Marie Curie to win a Nobel Prize.

Goeppert-Mayer and Mayer moved to San Diego, California, in 1960. They worked together at the University of California, San Diego. Shortly after arriving, Goeppert-Mayer suffered a stroke. Although she continued to research and teach at the university, her health gradually declined. Goeppert-Mayer died on February 2, 1972.

Graham, Bette (1924–1980)

Inventor Bette Nesmith Graham invented Mistake Out, a product generically called “white-out.” Her invention has helped many people save paper and time. She sold her company to Gillette Corporation 1979 for \$47.5 million.

Bette Nesmith Graham was born in Dallas, Texas, in 1924. Graham did not graduate from high school; instead, she went to secretarial school. Graham and her husband divorced after his service in World War II, and Graham had to raise her son, Michael, alone. In 1951, Graham became an executive secretary for the chairman of the board of Texas Bank and Trust. Graham was also a hobby painter and earned extra money painting store windows at holiday time.

As a secretary, she had to use an electric typewriter. Graham hated making mistakes on it. When she did, she had to retype the whole paper, because

mistakes couldn't be erased. Many of her fellow workers had the same issue. As a painter, Graham knew that mistakes could be covered up with more paint, and she used this idea to cover up a mistake at the electric typewriter. She invented a formula for the cover up fluid. Many of the secretaries noticed and asked for the formula so they could also use it when they made mistakes.

She decided she could make money from the formula and created a company called Mistake Out in 1956. When she was fired from Texas Bank and Trust for abandoning her duties at work, Graham focused only on her company. She obtained a trademark in 1958 and created a patent to protect her invention. She renamed her invention Liquid Paper and sold it from home. In 1968, she opened up a new plant and sold 1 million bottles. In 1975, she divorced her second husband and opened a 35,000 square-foot headquarters in Dallas.

Graham brought a unique sensibility to her business. She prioritized product quality over profits and practiced a humanistic management style that placed a higher value on employees than do many American businesses. Her company was one of the first to have an in-house child care facility. In 1979, she sold her company to Gillette for \$47.5 million and unfortunately died the year after.

When she died, half of her money went to charities, and the other half went to her son Robert Michael Nesmith, famed as one of the founding members of the pop rock band The Monkees. One of the charities she invested in was the Council on Ideas, a think tank dedicated to finding solutions to world problems. In 1989, Gillette reformulated Liquid Paper to make it less toxic. In spite of the computer and printer revolution, Liquid Paper is still on the market. Liquid Paper and another brand, Wite-Out, sell a total of \$120 million annually.

Hamilton, Margaret (1936–)

Born on August 17, 1936, Margaret Hamilton is a computer scientist, a business owner, and systems engineer. Most notably, she is the woman whose programming skills helped take men to the moon. She is also credited with creating the term “software engineering.”

Margaret Hamilton was born Margaret Heafield to Kenneth and Ruth Esther Heafield in Paoli, Indiana. In 1954, she graduated from Hancock High School. Four years later, she received her BA in mathematics with a minor in philosophy from Earlham College. She married her college boyfriend, James Cox Hamilton, and taught math and French in high school while he finished college. In 1958, she relocated and intended to study abstract mathematics at Brandeis University in Boston. She landed what was supposed to be an in-between job at MIT developing software for predicting the weather. Software engineering and computer science were not disciplines that could be studied at universities at the time. Instead, programmers learned on the job through hands-on experience.

On November 10, 1959, Hamilton gave birth to Lauren Hamilton. Being a working mother in the 1960s was not common, and being a woman in her field of work was even less common. Hamilton was seen on many occasions bringing her daughter with her to work. Lauren would sleep on the floor while her mother spent time creating programs.

From 1961 through 1963, she worked on the SAGE project, whose purpose was to create a computer system that could predict and track weather systems using simulators. The SAGE project was later developed for use by the military to detect and prevent potential Soviet air attacks during the Cold War. Hamilton's success on this program that no one had previously managed to create made her the perfect candidate for the lead developer position for the Apollo flight software.

She taught herself how to program computers and became the director of the Software Engineering Division of the MIT Instrumentation Laboratory (which later became known as the Charles Stark Draper Laboratory). She supervised a team of 100 mathematicians, engineers, technical writers, and programmers to develop the software for the Apollo 11 Guidance Computer.

The Apollo Guidance Computer was a chip-based computer with 64 kilobytes of memory and operated at 0.043MHz. The software was designed with the purpose of navigating to the moon and landing on it before navigating its return to Earth. This moon landing was one of the first examples of software playing such a crucial role in the completion of a mission. Because of the very restrictive weight, size, and power requirements, the program designers chose to utilize silicon chips. These were very expensive at the time, with an unknown reliability.

While her daughter, Lauren, was playing with a display-and-keyboard unit on a command module simulator, an error message popped up. Hamilton insisted on adding code to the program to prevent this error during a flight, even though there was no reason that a trained astronaut would ever do what her daughter had done. The idea was deemed unnecessary by NASA because astronauts are trained to be perfect and cannot make any mistakes. Instead, Hamilton was only allowed to add to documentation available to the astronauts and engineers that said, “Do not select P01 during flight.” What she was told many times would never happen *did* happen on the Apollo 8 flight. Without the precautions Hamilton had wanted to program, the navigation data was lost, and the computer would not be able to bring the astronauts home. After nine hours of troubleshooting, MIT coders were able to come up with new navigational data that was uploaded through Houston, bringing the astronauts home safely.

Hamilton is also credited with preventing Apollo 11 from becoming an aborted mission. Three minutes before Apollo 11 landed on the moon, the computers’ alarms went off because they were overloaded by incoming data. Simply put, the system was performing unnecessary tasks and recognized that this was an error. Hamilton’s insistence on the inclusion of a complete recovery program allowed the software to rank and prioritize tasks to stop lower-priority tasks and redirect power to the more important ones. In a letter written to *Datamation* in 1971, Hamilton insisted that the Apollo 11 landing would not have been successful without this programming.

In 1986, Margaret Hamilton became the CEO and founder of Hamilton Technologies Inc., which is based out of Cambridge, Massachusetts, not too far from

where her career began at MIT. According to the official company Web page, Hamilton Technologies was founded “to provide products and services to modernize the planning, system engineering and software development process to maximize reliability, lower cost and accelerate time to market.”

In 1986, she received the Ada Lovelace Award from the Association of Women in Computing. The moon landing had occurred in 1969, but it took over 34 years for NASA to recognize the crucial role that Hamilton played in computer science and taking men to the moon. In 2003, she received the NASA Exceptional Space Act Award. With it came a check for \$37,200. In 2009, she received the Outstanding Alumni Award from Earlham College. Across her career, Hamilton published 130 papers and reports in regard to her involvement with 60 projects and six major programs, all regarding software engineering and systems creation and management.

Thanks to Margaret Hamilton, software engineering has taken humanity beyond Earth’s atmosphere and laid the groundwork for nearly all modern human aspirations.

Haynes, Martha Euphemia Lofton (1890–1980)

Martha Euphemia Lofton Haynes was the first African American woman in the United States to earn a PhD in mathematics. Her father, a dentist educated at Spencian Business College (1886) and Howard University’s Dental College (1888), was a civil rights leader in the Washington, D.C., area. Her mother taught kindergarten in the D.C. public schools and raised both Euphemia

and a younger brother, Joseph, after a breakup with her husband in 1897.

Haynes's academic record speaks to her devotion to education, which continued throughout her adult life. She was the valedictorian at the M Street High School (1907) and Miner Normal School (1909) and then earned a BA in mathematics and psychology from Smith College (1914). She earned a master's degree in education from the University of Chicago (1930); her thesis was titled "The Historical Development of Tests in Elementary and Secondary Mathematics." She then earned a doctorate in mathematics from the Catholic University of America (1943). Her doctoral dissertation was titled "Determination of Sets of Independent Conditions Characterizing Certain Special Cases of Symmetric Correspondences." Her advisor was Aubrey Edward Landry, who is noted in the Mathematics Genealogy Project to have supervised at least two other successful female doctoral students, one as early as 1917. Haynes compared two methods of counting correspondences of rational curves in the projective plane, combining concepts from calculus and linear algebra.

As she pursued her degrees, Haynes taught in the District of Columbia school system, including at the elementary school, high school, and college levels. As a professor at Miner Teachers College in 1930, she created the Mathematics Department and served as its head for 30 years. Miner Teachers College was founded in 1851 as the Miner Normal School for Colored Girls. The school, though originally a primary school, began specializing in teacher training for black women not long after its founding. While Haynes was teaching, the school was part of the District of Columbia's racially segregated public school system. By the time Haynes retired in 1959, Miner Teachers College collaborated with Wilson's Teachers College to become the District of Columbia Teachers College. In 1976, that iteration of the college was absorbed into the University of the District of Columbia.

Haynes served as a member of the District of Columbia Board of Education from 1960 to 1968 and presided as its president from June 1966 to July 1967. During the civil rights era of the 1960s, Haynes advocated for poor students and fought policies that tracked African American students into vocational rather than academic programs.

Haynes was also involved in many community activities. She served as first vice president of the Archdiocesan Council of Catholic Women, as chair of the Advisory Board of Fides Neighborhood House, on several committees on social welfare, on the local and national committees of the United Service Organization, and as a member of the National Conference of Christians and Jews, the Catholic Interracial Council of Washington, the Urban League, the NAACP, the League of Women Voters, and the American Association of University Women. Haynes was awarded the Papal Medal—Pro Ecclesia et Pontific from the Catholic Church in 1959.

Haynes married Harold Appo Haynes (1889–1978) in 1917. Her husband, whom she had known since grade school, earned a doctorate in education from New York University (1946) and taught at Howard University from 1912 to 1918 before teaching and administrating in the District of Columbia School System. He died in 1978 at 89 years old. Euphemia Haynes died on July 25, 1980. Her obituary appeared in the *Washington Post*. The couple had no children. Haynes willed \$700,000 from her estate to the Education School at the Catholic University of America. Much of what we know about Haynes is contained in an archive of her personal and professional papers held at the American Catholic History Research Center and University Archives. Her achievements remain particularly notable because she became a professional mathematician at a time when not only women but also people of color were discouraged from studying math.

Hoover, Erna. See Telephone Switching, Computerized

Hopper, Grace (1906–1992)

Mathematician and U.S. Navy rear admiral Grace Murray Hopper was a pioneer in computer science. Hopper was one of the first programmers of the Harvard Mark I computer and developed the first compiler for computer programming language. She helped to create UNIVAC I, the first commercial electronic computer, and the naval applications for COBOL, or “common business-oriented language.” She is credited with popularizing the term “debugging.” Her nickname, “Amazing Grace,” came from the scope of her accomplishments and her naval rank.

Hopper was born Grace Brewster Murray in New York City in 1906. Her mother, Mary Van Horne, inspired her daughter’s passion for mathematics. When Hopper was seven years old, she took apart all of the alarm clocks in the house to find out how they worked. She was accepted at Vassar College in 1924 and studied mathematics and physics, graduating in 1928 with a bachelor’s degree in these subjects. She earned her master’s degree from Yale University in 1930 and married James Foster Hopper, a professor at New York University. Grace Hopper returned to Vassar in 1931 to teach mathematics, and three years later, she earned a PhD in mathematics from Yale. The marriage was less successful than Hopper’s career. James died during World War II, and the couple had no children.

In 1943, Hopper took a leave of absence from Vassar and joined the U.S. Navy Reserve. She was one of many women who volunteered to serve in the WAVES, or Women Accepted for Voluntary Emergency Service. Hopper graduated first in her class at the naval training school and then went to the Bureau of Ordnance Computation Project at Harvard, where she worked on developing the first electronic computer.

After the war, Hopper resigned from active service. In 1947, Hopper found a moth inside a Mark II Aiken relay calculator, which she and other operators saved and taped into the computer log with a notation that they had “debugged” the system. While Hopper is

Admiral Grace Hopper created the first compiler, invented the computer language COBOL, and helped develop the UNIVAC I and II. After she retired with the rank of admiral in 1986, the U.S. Navy named a missile destroyer in her honor. (U.S. Department of Defense)

generally credited with coining the term, the terminology of computer bugs had been around since Thomas Edison’s time. In an interview, Hopper said that she saved the moth and used the language because it fit into the existing lexicon.

Hopper remained at the Harvard Computation Lab until 1949, turning down a full professorship at Vassar to work as a research fellow at Harvard. In 1949 with the Eckert-Mauchly Computer Corporation, she worked as a senior mathematician on the team that developed UNIVAC I. In 1952, she started and accomplished her work on creating an operational compiler. This was innovational at the time, because it was widely believed that computers could be used only for arithmetic. In 1959, she served as the technical consultant for the committee, which defined the new computer language COBOL. It was Hopper’s belief that

programs should be written in a way that was more similar to English rather than machine code so that it was more accessible.

Hopper retired from the U.S. Navy Reserve as a commander when she was 60 years old. She was recalled to active duty to become director of the Navy Programming Languages Group. She retired again in 1971 but was again asked to return to active services in 1972 and was promoted to captain in 1973. In 1983, she was promoted to commodore by a special presidential appointment and was made rear admiral two years later. When she retired from the U.S. Navy in 1986 at 79 years old, she was the oldest active-duty officer in the navy.

Hopper continued to work in the computer industry until her death. She died in her sleep in 1992 and was interred with full military honors in Arlington National Cemetery. She is remembered as an innovative thinker for whom “we have always done it that way” was a poor reason to do anything. She was also a visionary who could see that computers could have much wider usage if programmers could create tools to make machines user-friendly. In that view Hopper must be credited as one of the people who made the 21st century’s easy-to-use personal computing devices possible.

Hydraulic Fracturing (“Fracking”)

The development of Marcellus shale into natural gas after 2007 relied on a number of new and emerging technologies. In each case, these innovations helped energy companies to transform a well-known

geological formation—shale layers deep below Earth’s surface—into natural gas that might be harvested and used as a relatively clean alternative to many other fossil fuels. Although this process might appear sensible and straightforward, one of these technologies—hydraulic fracturing—makes harvesting gas from shale deeply controversial.

The debate over hydraulic fracturing (or “fracking,” as it is also called) is focused on states currently working to harvest gas from the Marcellus shale formation, which is located primarily in the Mid-Atlantic region of the United States. Although there are a variety of problematic critiques related to fracking, its threat to underground water supplies may be the most acute. Unfortunately, threats to water supplies are an intrinsic portion of the fracking process.

The remarkable ability to frack deep below Earth’s surface begins with horizontal drilling. In the late 20th century, most oil and gas wells were drilled as vertical holes down through rock formations such as the Marcellus. Although a vertical gas or oil well could drain an area of about 10 to 40 acres, dense rock such as shale does not release its fluid or gas from a vertical hole drilled through it. Even though the Marcellus shale can be more than 900 feet thick, it does not achieve sufficient profile to release a significant amount of gas. Horizontal drilling creates a hole several thousand feet horizontally across the shale. After horizontal drilling creates such a hole, a hydraulic fracturing job, or frack job, is done on the newly drilled well. These technologies continue to evolve, and their product is therefore referred to as “unconventional” natural gas.

After casing or heavy pipe has been run into the newly drilled hole to line it, extremely high-pressure pumps are hooked up, and fluids (mostly water and sand) are forced down into the shale to open cracks and fissures so that more natural gas can flow out of the formation. The fractures allow the gas to seep into the well bore for collection. When the gas is produced in the shale and becomes pressurized, the pressure splits the rock. The Marcellus shale is chock-full of natural fractures, making it easier for gas companies to extract gas. “Fractures are good for business,” says one industry scientist. “If you have enough natural fractures, it’s much cheaper to drill a production well than if you do not have them.”

Hydraulic fracturing is the primary completion process used in the Marcellus shale. It has been the subject of controversy lately, with environmental groups protesting the drilling of new wells in the environmentally sensitive Chesapeake Bay watershed, among other areas. Wells in the Marcellus formation are as deep as 9,000 feet, and the productive zone is far below any water aquifers. A properly cased gas well, lined with thick steel pipe and cemented into place, will ensure a safe frack job. State and federal agencies monitor the process of casing and testing new wells and hydraulic fracturing. The source of contention among environmental groups is the number of chemicals pumped into the formation along with frack water and sand. Up to 50 percent of this fluid may remain in the ground; however, it may take millions of years for any of it to migrate upward to water-bearing zones. If proper safety measures are undertaken, hydraulic fracturing can be a safe means of producing Marcellus shale gas wells.

The impact of hydrofracking on surface water and groundwater is cause for great concern. About 5 million gallons of water per well are used to make fracking fluid, a mixture of water, sand, and hundreds of other possible chemicals, including such hazards as benzene, formaldehyde, arsenic, and diesel fuel. Some frack water stays in the ground, and some is returned to the surface.

This flowback accumulates higher concentrations of salts and minerals and sometimes radioactive contamination. Wastewater treatment plants cannot remove many of these pollutants. Some flowback is reused for fracking, but more is stored in huge artificial ponds. Spills occur during water transport and storage. Improperly cased wells leak frack water and methane into the water table, polluting public and private wells. Pennsylvania waterways drain into the Chesapeake Bay, so gas drilling increases the bay's pollution problems. Storm water erosion carries increased silt loads from dirt roads and drill sites. Minerals from frack water discharged into streams and rivers increase total dissolved solids in the bay.

Some regulations are in place to reduce the problems caused by drilling for shale gas. New laws are being proposed and vigorously debated.

Currently in Pennsylvania, setbacks are required between gas wells and water sources. Drillers must acquire permits, submit plans, post bonds, and notify

landowners whose water supply is within 1,000 feet of a gas well. Gas wells must be cased to prevent contamination of the groundwater table. Pennsylvania's Oil and Natural Gas Act prevents local municipalities from regulating drilling activities but allows local zoning of well placement.

In 2010, a bill proposed the repeal of exemptions from clean water and environmental impact regulations allowed to gas drillers by the 2005 Federal Energy Policy Act and required disclosure of frack water chemicals, but the bill died in committee. In 2011, SB 1100 proposed somewhat stiffer requirements to safeguard water sources and surface owners' rights and requires impact fees to mitigate landowner and community problems. The bill imposes no gas revenue tax, contrary to the wishes of most Pennsylvanians.

The history of coal mining shows the long-term costs of shortsighted extraction policies. Pennsylvania alone has 9,000 abandoned mines and acid mine drainage that pollutes 2,500 miles of streams. The projected cleanup cost is \$15 billion. Awareness of these consequences can help Pennsylvanians choose better ways to benefit from our newest energy boom.

Hydrogen Energy

Hydrogen is considered the simplest element and is one of the most abundant elements in the earth's crust. It composes about 75 percent of the universe. Natural hydrogen never stands alone; it is always associated with other natural elements. Hydrogen has the highest energy of any common fuel by weight but the lowest

energy content by volume. It is also the lightest element. To get energy from hydrogen, we have to mix it with oxygen to create a chemical reaction, which then creates hydrogen energy.

Fuel cells convert the chemical energy in hydrogen to electricity, with pure water and heat as by-products. Fuel cells are known to be up to three times more efficient than other traditional technologies, which usually generate around 35 percent of the energy of fuel cell systems, up to 60 percent. Fuel cells continue to produce energy as long as hydrogen is supplied, but they work best with pure hydrogen. Also, fuel cells work quietly, have fewer moving parts, and pollution is lower with them, because the system is pollution free. Fuel cells can power anything that batteries can power.

Since the 1970s, the NASA program has relied on hydrogen gas for rocket fuel to take crews and cargo into space. The space program used liquid hydrogen to power the electrical systems of shuttles as well as to launch them and other rockets into orbit. One program used around 500,000 gallons of cold liquid hydrogen with other operations to burn rocket engines of each shuttle flight. Fuel cells were one component of powering space shuttles, contributing to the production of a clean by-product—pure water—for the shuttle crew.

IBM 360 Computer

The 1964 New York World's Fair would be the launching point for a revolution in business computing. The crown jewel of the IBM pavilion was the million-dollar-plus IBM 360 computer and a dramatic introduction of the computer to the general public. The IBM 360 family of computers was designed to do a

variety of tasks for businesses, including administrative and engineering tasks. IBM promised basic software that allowed for future upgrades. This common instruction-set architecture was revolutionary for the time and is taken for granted today.

The IBM pavilion at the World's Fair had a 500-seat theater on hydraulic lifting rams, pushing the audience to the rooftop to view a nine-screen film on the workings of a computer. The fair had over 10 million visitors. The exhibit allowed the first interaction with a computer for members of the public. Questions about history were asked for the computer to respond to. The development costs of the IBM 360 computers were in the billions, exceeding the development costs for the nuclear bomb. IBM believed the 360 series would open up the commercial market for the computer, which had been dominated by government and military contracts. It was an investment that would assure IBM's dominance in business computers for decades. The original price for units ranged from \$135,000 to \$500,000. The first commercial customers were insurance companies, banks, and the accounting departments of large manufacturing companies such as United States Steel.

While the IBM 360 was a revolutionary product, it was an evolutionary result of IBM's business model. In fact, IBM's business model has been one of evolving business machines for decades, moving from hand calculators to electromechanical devices to electronic calculators. IBM had a long history in data analysis and business calculations going back to the 1890 census. Herman Hollerith had designed a punched data card to tabulate experimental counts for the 1880 Tabulating Machine Company. The company won government contracts to analyze census data but looked for commercial business applications for the machines at companies such as the railroads. In 1914, Thomas Watson was brought in from National Cash Register to head the then Computing Tabulating Recording Company. The company had been formed in 1911, which is the official formation date of IBM; its name was changed to International Business Machines Corporation in 1924. In 1920, IBM introduced its first machine—the printing tabulator.

Like high-tech companies today, IBM formed educational and creativity programs for employees to

develop new products. By the 1930s, IBM was making time clocks, job recorders, time stamps, and dial recorders. In 1935, IBM won the contract for the world's biggest accounting project, known as the Social Security Act, using its "super-computing machine." IBM had also introduced the first electric typewriter, which would be a core product for the company for decades. These two technologies would be key roots of the evolution of the IBM 360.

These technologies were merged to create the first electromechanical calculator in the late 1930s. During World War II, IBM invested heavily in research, resulting in the release of the IBM 603, the first commercial product to use electronic arithmetic circuits. In the 1950s, IBM started using magnetic tape as storage for its calculators. While large computers such as the Universal Automated Computer (UNIVAC) were focused on specific applications, IBM wanted flexibility in its large computers. A programming language known as FORTRAN was released in 1957, allowing the computer to be used for different operations based on formula calculations. This would be a key evolutionary step in the development of the IBM 360.

The 1960s brought huge investment in research and development, which resulted in applications such as its report program generator. The 1962 IBM 7090 was developed to help airlines manage their reservation systems. The work on this project would lead to the IBM 360. IBM was then the largest computer company in the world, with over 100,000 employees, and it controlled 70 percent of the market. The company was gambling billions in research for its IBM 360 system. The competition of Burroughs, National Cash Register (NCR), Eckert–Mauchly Computer Corporation (makers of UNIVAC), Control Data, General Electric, Radio Corporation of America (RCA), and Honeywell, known as the "seven dwarfs," were letting IBM take the research lead. The research-and-development costs for the IBM 360 are still considered the highest for any product development project by a private company. Many inside IBM thought the IBM 360 would never recoup the huge investment. The risk was really overstated, since IBM had been taking steps toward the IBM 360 for over 50 years. Its evolutionary-step research business model would become the standard for corporate research

managers. Using this approach to research a project would produce a development tree of new products.

The IBM 360 would be a huge success, and research on the project would lead to the magnetic tape typewriter, NASA computer systems, memory chips, and fractals, which would lead to computer animation. The IBM 360 became the heart of America's space program. It found a home in most of America's accounting and engineering departments. IBM sales increased more than fivefold. The company was so dominant that its architecture became a standard. The cloning of the IBM 360 by Soviet spies assured that the IBM architecture would become a world standard. The IBM 360's success brought the number of company employees to 270,000 and its sales to over \$7 billion by 1970.

The gigantic success of the IBM 360 would bring a new problem. The U.S. government filed an antitrust suit in 1969, stating that IBM had violated the Sherman Anti-Trust Act. The case would drag out for 13 years (*United States v. International Business Machines Corp.*) and impact IBM's managerial and product decisions. Eventually, the government dropped the case, but IBM did open its systems and training up to allow the development of independent companies to provide services for IBM hardware. With its failed entry into the copier market, IBM showed that size alone did not guarantee new product success. Finally, in the 1980s, Apple and Microsoft took down the giant of the PC business.

In Vitro Fertilization (IVF)

In 2010, Robert Edwards won the Nobel Prize in Physiology or Medicine for the development of in vitro fertilization (IVF). Although the prize was ultimately awarded to a British scientist, the development of IVF was an international endeavor that required collaboration between scientists from England, Australia, and the United States.

In 1965, Edwards, working with a married pair of United States scientists, Georgeanna Seegar Jones and Howard Jones at Johns Hopkins Hospital, published their attempts to fertilize human ova in vitro. Edwards also worked with Patrick Steptoe, a gynecologist working the United Kingdom, to develop a less invasive laparoscopic surgery to harvest mature human eggs. Edwards's collaboration with Steptoe produced a fertilized human egg in vitro.

Implantation studies began in 1973, when Carl Wood and John Leeton of Australia reported the first human IVF pregnancy—which resulted in early miscarriage. In the same year, American scientists Landrum Shettles and William Sweeney attempted IVF in an infertile couple, Doris and John Del-Zio. Eggs and sperm were harvested and combined, but hospital administration prevented Shettles from implanting the embryos. Doris Del-Zio later sued the hospital for “intentional infliction of emotional distress.” The U.S. government subsequently passed legislation preventing IVF research pending approval from a National Ethics Advisory Board. Funding for IVF research did not continue until March 1979.

Edwards and Steptoe continued their work in the United Kingdom and, in 1978, their work produced the first-ever IVF birth when baby Louise Brown was born in Oldham, England, on July 25, 1978. In 1981, Howard and Georgianna Seegar Jones of Eastern Virginia Medical School achieved the first IVF birth in the United States: Elizabeth Carr. Their technique, called “controlled ovarian hyperstimulation” (COH), used hMG, a follicle-stimulating hormone that increased the production of oocytes.

By 2006, IVF, also called assisted reproductive technology (ART), produced 54,656 infants, or 1 percent of total U.S. births. In 1984, Jones helped establish an ethics panel to guide its practices, and it is now part of the American Society for Reproductive Medicine.

Georgianna died in 2005. By the time Jones died in 2015, about 4,000 IVF babies had been born with assistance from the clinic the Joneses established, and fertility treatments there have helped thousands of other families.

Integrated Circuit

The integrated circuit, invented in 1958 and commonly known as the microchip, revolutionized electronics, making possible modern digital technologies.

Before the integrated circuit, the electronics industry relied on vacuum tube technology. But vacuum tubes presented many difficulties: they were easily broken, bulky, unreliable, power hungry, and produced considerable heat. In 1947, Bell Telephone Laboratories developed the transistor, which overcame many of the drawbacks of vacuum tubes. In comparison to vacuum tubes, transistors were sturdy, compact, more reliable, more energy efficient, and produced less heat. Engineers were able to design more complex electronic circuits with hundreds or thousands of discrete components such as transistors, diodes, rectifiers, and capacitors. However, these components still had to be interconnected to form electronic circuits, and hand-soldering individual components to tiny bits of wire was expensive and time-consuming. Also, each of these soldered joints could potentially be compromised, causing a circuit to fail.

Jack Kilby, an electrical engineer at Texas Instruments, took on the challenge of finding a cost-effective, reliable way to produce and interconnect these components. In 1958, he developed the first working integrated circuit. Instead of using separate transistors, resistors, and capacitors to form a circuit, Kilby's

integrated circuit combined a transistor, a capacitor, and the equivalent of three resistors all on the same chip. This first integrated circuit utilized a thin slice of germanium as a bulk resistor and contained a single bipolar transistor. It had four input-output terminals, a ground, and wires composed of gold. Kilby fabricated three types of circuits to test his idea: a flip flop, a multi vibrator, and a phase shift oscillator.

While Kilby was developing his integrated circuit technology, Robert Noyce of Fairchild Semiconductor was also working on a solution. His approach was to use a photolithographic printing technology known as the planar process, which made his circuit easier to manufacture than Kilby's. Noyce's invention debuted five months after Kilby was issued his patent for the integrated circuit. In 1959, both Kilby and Noyce were named as inventors of the integrated circuit in their companies' applications for patents. Years of litigation resulted in Fairchild and Texas Instruments agreeing to cross-license their technologies.

Without the integrated circuit, which has been called the single most important invention of the information age, computer technology as we know it now would not be possible. Microelectronics are the basis for all modern technology, powering desktop, laptop, and mainframe computers as well as communications equipment and controlling everything from cars to advanced machinery. Internet technology is dependent on the integrated circuit for high-speed digital communications, satellite transmissions, and multifunctional wireless handheld devices.

Intel Corporation

Founded in 1968, Intel Corporation is an American multinational technology company based out of Santa Clara, California, in the heart of Silicon Valley. Founded by Gordon Moore and Robert Noyce, Intel

Corp. is the world's largest producer of semiconductor chips and the inventor of the most common processing chip found in most personal computers. Lenovo, Apple, Dell, and HP are a few of the examples of computer companies that Intel Corporation supplies with chips. In addition to processors, Intel also manufactures motherboard chipsets, network interface controllers, graphic chips, and many other products as well as communications and computing devices.

Intel Corporation was founded on July 18, 1968, by Robert Noyce and Gordon Moore. A chemist who, along with seven other men, had founded Fairchild Semiconductor 11 years before Intel, Moore served as Intel's first executive vice president. Moore is the author of "Moore's Law," which says that the number of transistors in a dense integrated circuit will double every two years. Technology companies use Moore's Law to plan long-term strategies in product development. Robert Noyce, another cofounder of Fairchild Semiconductor with Moore, is often cited as the person responsible for the first integrated circuit (microchip). Jack Kilby, who worked at Texas Instruments, is also so credited.

Moore and Noyce also worked with Hungarian American Andrew Grove, noted engineer and businessman. Like Moore and Noyce, Grove worked at Fairchild Semiconductor and left that company along with Moore and Noyce when they began Intel. Andrew Grove was Intel's first director of engineering and helped transform the company into the world's largest manufacturer of semiconductors. Another Hungarian American, Leslie L. Vadasz, made up the fourth of Intel's original employees. He was at the head of the department that developed the Intel 4004, a four-bit central processing unit (CPU) that became Intel's first commercial success in microprocessors.

Arthur Rock provided Noyce and Moore with start-up capital and helped the men find investors. Two years after its founding, the company went public. Originally, the founders planned to call the company "Moore-Noyce," but they feared the name sounded like "more noise," so they took the first letters from "integrated" and "electronics" to make "Intel."

At first the company made semiconductors, but it quickly branched out to SRAM and DRAM memory chips. SRAM and DRAM are types of semiconductor memory that use bistable latching circuitry to store each bit. SRAM displays data remanence—data that is

eventually lost when the memory is not powered. DRAM, on the other hand, is dynamic random-access memory that must be periodically refreshed. SRAM is more expensive than DRAM. SRAM is typically used for computer CPUs to reduce the average cost of access to the main data from the main memory, while DRAM is used for a computer's main memory. SRAM and DRAM represented the majority of Intel's business until 1981.

Intel also created the world's first commercial microprocessor chip in 1971. It was not until the success of the personal computer that chips became its primary business. At first, Intel provided microchips to IBM and then to other companies in the personal computer market. Intel invested a large amount in new microprocessor designs, causing the rapid growth of the computer industry during the 1990s. By marketing their processors under the name "Pentium," Intel developed customer brand loyalty.

In the 2000s, Intel lost its dominance to competitors, particularly Advanced Micro Devices (AMD). Attempts to diversify the company proved unsuccessful.

The company was known for having aggressive tactics in defense of its high market position, often crushing smaller companies with intellectual property rights lawsuits. Even when Intel lost, it won because competitors could not afford the legal fees it took to fight a company as powerful as Intel. AMD has accused Intel of unfair competition and has brought a number of lawsuits against the technology behemoth. Intel has also had several struggles with Microsoft for control over future directions in the personal computer industry.

In 2008, Intel introduced its first solid-state drives (SSDs), solid-state devices that store persistent data (data that outlives the process that made it). Intel continues to improve its SSDs, such as with a 2015 plan to market a consumer PC with an SSD drive. In the 2010s, Intel has made a significant number of corporate acquisitions, including of McAfee computer security and Infineon's Wireless Solutions in 2010, Password Box in 2014, and Vuzix, a "smart glass" company in 2015.

In 2002, President George W. Bush gave Gordon Moore a Presidential Medal of Freedom for his contributions to technology and science, and in 2008, he was inducted into the Computer History Museum. Robert

Noyce died in 1990. The Noyce Foundation provides funding for mathematics and science education for American children.

Jackson, Mary Winston (1921–2005)

Starting as a "computer" for the segregated, all-black West Area Computing division at Langley Research Center in 1951, Mary Jackson became NASA's first black female engineer. She was recruited by the National Advisory Committee for Aeronautics (NACA) in 1951 for her mathematical knowledge and computation ability. She is notable for breaking social expectations for both women and African Americans. She is also known for her role in promoting women in NASA's science, engineering, and mathematical careers.

Born in Hampton, Virginia, on April 9, 1921, Jackson was the daughter of Ella and Frank Winston. She graduated from the all-black George P. Phoenix Training School with the highest honors and later earned her bachelor's degree in mathematics and

Mathematician Mary Jackson, the first black female engineer at NASA, at work at NASA Langley Research Center in Hampton, Virginia, in 1977. (Bob Nye/NASA/Donaldson Collection/Getty Images)

physical science from Hampton Institute in 1942. After graduating, she became a tutor for high school and college students before being recruited by NACA as a research mathematician, or “computer.” A “computer” was needed to compute and check mathematical calculations used by the Guidance and Navigation Department.

In 1953, she accepted an offer to work for engineer Kazimierz Czarnecki in the Supersonic Pressure Tunnel. Kazimierz was impressed by Jackson’s work and encouraged her to take graduate-level courses to qualify for the open engineering position. Relevant classes at the time were offered only by the University of Virginia, which held night classes at the all-white Hampton High School. Jackson successfully petitioned the City of Hampton to allow her to attend them. After the completion of these courses, Jackson was promoted to aerospace engineer in 1958 and

became the first black female engineer at NASA. Throughout her career, she worked in many divisions, including the Compressibility Research Division, Full-Scale Research Division, High-Speed Aerodynamics Division, and the Subsonic-Transonic Aerodynamics Division.

Jackson achieved the most senior engineering title in her 34 years at NASA but took a demotion to become a manager of both the Federal Women’s Program and the Affirmative Action Program. These roles gave her the opportunity to influence the hiring and promotion of women in STEM careers. Jackson also served as a Girl Scout leader for more than 30 years and is noted for helping children in her community build a miniature wind tunnel for testing airplanes.

Jackson was married and had two children, and she continued her work at NASA until she retired in 1985. This work includes 12 authored and coauthored

technical papers for NACA and NASA and many technical awards, and she advised women and other minorities on career advancement. She died on February 11, 2005, at the age of 83. Her legacy continues today in the 2016 film *Hidden Figures*—which is a recounting of Jackson’s career, specifically on the Apollo missions—and in the career of every female engineer following in her footsteps.

Jet Propulsion Laboratory (JPL)

The Jet Propulsion Laboratory (JPL) is a federally funded research-and-development center. It is a part of a public-private partnership with the U.S. government. Its main purpose is conducting research and experiments for the government, which funds it. It is also part of the National Aeronautics and Space Administration (NASA), an independent agency belonging to the U.S. government that conducts research for the U.S. space program and in the aerospace field. JPL currently employs and is operated by many at the California Institute of Technology.

Surprisingly, JPL appeared many years before NASA was even formed. A lot of their research goes toward similar goals. The JPL has two main facilities in La Cañada Flintridge and Pasadena, California. Despite its name, JPL does not mainly focus on jets or propulsion. The lab’s main area of focus is on the development and operation of planetary robotic spacecraft, also known as space probes. Robotic spacecraft are sent from Earth to explore the moon, planets, or other things in the solar system. Their main purpose is to gather information, and they are designed based on

what kind they need to gather and measure. NASA and JPL determine what kind of data they want to research.

The Jet Propulsion Laboratory was almost accidentally created in the mid-1930s. Some rocket enthusiasts, most of whom were students at the California Institute of Technology, began to experiment, leading to an explosion. They moved their work out to La Cañada Flintridge, California, where one of the JPL facilities exists today.

The “Space Race” between the United States and the Soviet Union is one reason that JPL rose to prominence in space exploration. In January 1958, JPL was responsible for creating and launching a spacecraft known as Explorer 1. Working alongside the U.S. Army, JPL created the first-ever American satellite. Ten months later, NASA was founded on October 31, 1958, and the army transferred its work to it.

Since then, JPL has been a part of or led countless space missions. In the early years of space exploration, JPL focused on big missions to reach as far as possible and encounter other planets in the solar system. JPL took part in NASA’s Viking program to Mars, one of our neighboring planets. Spacecraft created by JPL went to Mars to study the planet from both space and the surface. The two space probes each had two parts; two parts would orbit Mars while the other two were on the surface. The two space probes were launched on August 20 and September 9, 1975, respectively. They both reached their destination roughly 10 months later.

These space probes gathered large amounts of new information about Mars. JPL was a part of this mission that would bring the United States more understanding of outer space than ever. The probes took close and clear images of Mars’s surface, addressing perennial questions about life on Mars and whether it could sustain human life. The findings showed that water may once have existed on Mars. The terrain and geological forms indicated that rivers and lakes may once have existed, as huge valleys and canyons were found carved into the ground. The erosion of the landscape resembled the erosion we see here on earth where rivers and streams once flowed.

The Jet Propulsion Laboratory was very successful in its early missions, which encouraged further exploration and elicited excitement and approval from the government and people who wanted to learn more. Another well-known large space mission that JPL developed robotic spacecraft for and involved NASA

was the Voyager Cassini-Huygens project. The craft made its trek to a planet nearly 800 million miles away from Earth: Saturn. Cassini was the name of the spacecraft that would orbit Saturn, and the Huygens was the craft that would land on Saturn and probe it. The spacecraft began development at the Jet Propulsion Laboratory and eventually was launched on October 15, 1997. It finally reached Saturn nearly seven years and three months later on January 14, 2005. This landing would be the first ever of any robotic spacecraft on a planet at the outer layer of the solar system.

JPL's Cassini-Huygens had a few jobs to do. JPL and NASA, as well as a few European countries, wanted to learn as much as they could from Saturn, and the spacecraft they built was perfect for gathering information and data. One of the things people are most curious about are Saturn's rings. NASA and JPL most wanted to understand their structure and behavior. They also wanted to collect information on the atmosphere, weather, and material of Saturn as well as its moons. The probe on the planet communicated with scientists by sending signals to the orbiter, Cassini, and the orbiter relayed the data to Earth. Just over 19 years ago, the Cassini-Huygens spacecraft went to Saturn, and it is still hard at work today, gathering data.

Perhaps one of the most notable and well-known space probes is the Curiosity Rover, also developed with the help of the JPL. In the second decade of the 21st century, the obsession with Mars has been at an all-time high. Did Mars ever have a climate like Earth's? We also want to know if humans can inhabit Mars. The Mars Science Laboratory launched by NASA in late November 2011 is headed by JPL; its goal is to learn about Mars, its geology and climate, and ultimately whether or not water plays a role on the planet. The robotic spacecraft created by JPL scours the landscape of Mars, collecting data. With its computers and cameras the Curiosity Rover communicates in several ways. An X-band system as well as a UHF radio transmit signals that are received on Earth by antennas at the Goldstone Deep Space Communications Complex, which JPL also created. Curiosity's current mission is to gather information on the biological, geological, and geochemical nature of Mars.

The Jet Propulsion Laboratory has contributed greatly to the knowledge and advancements in space

exploration and science that help us understand our solar system and things in it as close as our moon or as far as planets millions of miles away. JPL's work will be valuable even hundreds of years from now. If one day humans inhabit Mars, JPL will have contributed to the possibility. It has allowed us to believe in and do much that we once thought was impossible in regard to exploring our solar system.

Johnson, Katherine Goble (1918–)

Born on August 26, 1918, in White Sulphur Springs in West Virginia, Katherine G. Johnson, née Katherine Coleman, is a remarkable African American mathematician and computer scientist whose life has been punctuated by a series of major breakthroughs and contributions to U.S. aerospace programs.

Johnson exhibited brilliance in mathematics at a young age and, combining that with a love for learning, she graduated early from high school and entered West Virginia State College at 15 years old. She found a mentor in renowned Dr. William W. Schiefflin Claytor, the third African American to earn a PhD in mathematics. He was so impressed by her intelligence and vivid passion that he made it his mission to prepare her to become a research mathematician, designing a class in the analytic geometry of space specifically for her. She graduated at age 18, summa cum laude, with bachelor of science degrees in mathematics and French.

Since the depression still lingered, teaching was the only stable job for educated black women.

Therefore, Johnson joined the workforce as a teacher of math and French. In 1937, she was selected to be one of the three black students to integrate West Virginia's graduate school in Morgantown. However, she opted out of finishing the program because the environment proved unfavorable for her. In 1930, she married James Francis Goble and had three daughters: Joylette, Katherine, and Constance.

In 1952, she found out from a relative that the National Advisory Committee for Aeronautics (NACA) Langley laboratory had open positions at the all-black West Area Computing section. The division was headed by Dorothy Vaughan, a fellow Virginian, and made up of African American women who served as "computers." A computer was needed to compute and check mathematical calculations used by the Guidance and Navigation Department of NACA. She applied for the position and was accepted the following year. She began working there in 1953, and her expert calculations and notable curiosity enabled her to stand out. She not only wanted to do the job but also wanted to know the main reason behind it, asking numerous questions to gain better understanding. She was soon moved from the computing lab to Langley's research division, where she spent the next four years analyzing flight test data. It was in late 1956 that her husband died of cancer, and despite the challenges at home, she succeeded at her job, earning the respect of her male colleagues.

At the beginning of the Space Race in 1958, NACA reformed into the National Aeronautics and Space Administration (NASA). Johnson was one of those assigned the task of determining how to get a human into space and back. She remained a key asset to NASA with her consistent accuracy in trajectory calculations for the historic Apollo 11 trip to the moon and back in 1969, her participation in the development of the Space Shuttle program and Earth Resources Satellite, and other work until her retirement in 1986. Johnson has been presented with an assortment of awards and honorary degrees, including the Presidential Medal of Freedom, the highest civilian honor, by Barack Obama in November 2015. The following May, NASA opened the 40,000-square-foot Katherine G. Johnson Computational Facility at Langley.

Kilby, Jack (1923–2005)

Jack Kilby is best known as the inventor who revolutionized the electronics industry by developing the integrated circuit, or microchip, which allowed computers to become smaller and more affordable, launching the digital age.

Kilby grew up in Great Bend, Kansas. His father ran a small electric company, and Kilby became interested in electronics in high school when his father had to work with amateur radio operators to communicate with isolated customers who had lost power and phone service during an ice storm. He decided to apply to the Massachusetts Institute of Technology's electrical engineering program, but his scores on the entrance exam fell slightly under the cutoff, and so he was unable to enroll. Instead, he joined the army and was stationed at a radio repair shop in northeast India.

After returning from the service, Kilby used his GI Bill to major in electrical engineering at the University of Illinois, graduating in 1947, one year before the invention of the transistor, which would entirely change the direction of electronics innovation.

After his graduation, Kilby first worked for an electronics manufacturer in Milwaukee, Wisconsin, that made radio, television, and hearing aid parts. While working there, Kilby earned his master's degree in electrical engineering. In 1958, Kilby took a position with Texas Instruments, where he was allowed to work in his area of interest—electronic component miniaturization.

During the summer of 1958, the Texas Instruments facility was only sparsely populated because

most of the researchers were on vacation. With few distractions, Kilby had the time he needed to conceptualize the integrated circuit. He realized that all the parts of a circuit, not just the transistor, could be made out of silicon. Basically, the integrated circuit united the three components—a transistor, a capacitor, and the resistors—on the same chip, making it significantly smaller and more easily produced. Kilby's boss authorized him to pursue the idea, and by September 12, Kilby had built a working model. On February 6, Texas Instruments filed a patent for the invention.

Five months after Kilby was issued his patent for the integrated circuit, Robert Noyce of Fairchild Semiconductor also developed a similar device. Noyce's integrated circuit used a photolithographic printing technology known as the "planar process," which made it easier to manufacture than Kilby's—which used germanium and individual wires. In 1959, both Kilby and Noyce were named as inventors of the integrated circuit in their companies' applications for patents. Years of litigation resulted in Fairchild and Texas Instruments agreeing to cross-license their technologies.

After the invention of the integrated circuit, Kilby went on to lead the first groups that incorporated integrated circuits into military systems and computers. He was also involved with teams that invented the handheld calculator, the first widely available consumer electronic to use the integrated circuit, and the thermal printer. In 1970, he worked on a solar power-generating project that incorporated silicon technology.

Kilby served as the distinguished professor of electrical engineering at Texas A&M University from 1978 to 1984. By the end of his career, he held more than 60 U.S. patents. Kilby was awarded the Nobel Prize in Physics in 2000. (Kilby said that he was sure that if Noyce were alive, he would also have been nominated to share the prize.) Other awards included the National Medal of Science and induction into the National Inventors Hall of Fame. Kilby's first simple circuit spawned a world information industries market now worth more than \$1 trillion annually. Kilby died in 2005.

Kwolek, Stephanie Louise (1923–2014)

Stephanie Kwolek invented a polymer that is manufactured by DuPont under the trade name "Kevlar." After graduating from college, she took what was supposed to be a temporary job at DuPont while saving money to attend medical school. Her work was so interesting, however, that she stayed on with the company and became involved in the research that led to the discovery of low-temperature polymerization. She gained national attention in 1960 for her work creating long molecule chains at low temperatures and her discovery of the method to spin synthetic, petroleum-derived fibers in a liquid crystalline solution. The compound had such high tensile strength that she ran the tests again and again to make sure she had not made an error before reporting her discovery to the laboratory director. The resulting product, Kevlar, eventually led to a multimillion-dollar industry with more than 200 commercial applications, including use in radial tire cords, composites, rope, thermal-insulating clothing, and bulletproof vests. At the time of her retirement, Kwolek owned 17 U.S. patents.

The use of Kevlar in bulletproof vests has earned Kwolek many fans and accolades. More than 2,000 police officers whose lives were saved due to wearing Kevlar vests formed a Survivors Club, a joint venture between DuPont and the International Chiefs of Police Association. Kwolek was regularly contacted by individuals thanking her and even asking for an autograph. Even after her retirement, Kwolek continued to consult with DuPont, as well as to give public and school lectures about careers in science. In 1996, she was featured along with other DuPont employees in a series of print and television ads describing the company's research.

Kwolek was elected to the National Academy of Engineering in 2001 for “the discovery, development, and liquid-crystal processing of high-performance aramid fibers.” She won an early publication prize from the American Chemical Society (1959) and also received the Creative Invention Award of the ACS (1980) and the Perkin Medal of the Society of Chemical Industry (1997), only the second woman to receive that prize. She was inducted into the National Inventors Hall of Fame (1995) and the Women in Technology International (WITI) Hall of Fame (1996). She received the nation’s highest technology honor, the National Medal of Technology (1996), and honorary doctorates from Worcester Polytechnic Institute (1981) and the University of Delaware (2008). She was a member of the American Chemical Society and American Institute of Chemists.

Lacks, Henrietta (1920–1951)

Born Loretta Pleasant on August 1, 1920, in Roanoke, Virginia, Henrietta “Hennie” Lacks is known for her “immortal” HeLa (pronounced hee-la) cells that were taken from her without her permission, cultured, and used for research. Lacks died from cervical cancer in 1951, but her cells and her story live on, as does the discussion of medical ethics that surrounds her story.

Lacks came from a poor African American family and was four years old when her mother died. Her father, Johnny, realized that he was not able to take care of all his children on his own, so he sent them to live with relatives. Lacks ended up with her grandfather, Tommy Lacks, who lived in a log cabin, where she had to share a room with her nine-year-old cousin, David “Day” Lacks. Day attended school until third

grade, and Henrietta attended until sixth grade. They worked on their grandfather’s tobacco farm along with many of their other cousins. When Henrietta was 14 years old, she had a child with Day. The couple married in 1941 and had several more children. They also moved to Maryland so Day could work at a steel mill, a job that paid more than sharecropping.

After Henrietta Lacks’s last child was born, she experienced uncontrollable vaginal bleeding. She discovered a lump on her cervix and told Day about it, and they went to see the local doctor. Initially the doctor believed that the lump was from syphilis, but the test for syphilis turned out to be negative. He referred her to Johns Hopkins Hospital, the closest hospital to where the Lackses lived that treated African American patients. Lacks saw gynecologist Howard Jones, who took some tissue samples. In 1951, Lacks was diagnosed with epidermoid carcinoma of the cervix, or cervical cancer.

Jones called his boss, Richard TeLinde, who wanted to compare normal cervical tissue to two types of cancerous tissues. For this, he called the head of tissue culture research at Johns Hopkins Hospital, George Gey. Lacks was an independent woman, so she did not tell her husband that her lump was malignant; she told him that she was going to get treated and would be okay. One of Lacks’s shavings was normal, and the other was cancerous; they were placed in glass dishes and given to Gey so he could try to culture them. It turned out that Lacks’s cancerous cells were able to divide and grow in lab culture material, something no other human cells had ever done.

Scientists were tremendously excited about the research possibilities that could arise from having living cell cultures and began to propagate and sell the HeLa cell cultures to scientists around the nation and the world. Today, there are so many HeLa cells that scientists say that if the cells were lined up end to end, they could to wrap around the earth three times. Lacks’s aggressive cancer killed her just months after her diagnosis on October 4, 1951, at Johns Hopkins Hospital in Baltimore, Maryland. Lacks never knew that her cervical cells had become a commodity, nor did she share in any HeLa profits.

Lacks’s cells have played a crucial role in many scientific breakthroughs. Experimentation on HeLa

cells made it possible for scientists to find cures for some cancers, develop a polio vaccine, learn what happens to cells in space, and more. Nonetheless, Lacks's case illustrates a lapse in scientific ethics in that scientists used her cells without her knowledge or permission, gave her no credit, and allowed her no share of profits from their use. In the 1970s, the HeLa cells came to the Lacks family's attention when scientists asked for more information about their genetics. Racial issues complicated the Lacks case, as critics pointed out that the science and medical fields had a record of abusing African American patients and test subjects. In the 1990s, newspaper articles and a one-hour documentary brought Lacks's case significant attention. Two books further explored the story of both Henrietta Lacks and her HeLa cells. In 1991, the California Supreme Court ruled that it was legal to commercialize a person's "discarded" cells, but scientific ethicists continue to discuss the scientific community's responsibility to test subjects.

Land, Edwin H. (1909–1991)

Edwin H. Land, best known for his development of the Polaroid camera, was a prolific inventor and businessman who developed optical, photographic, and military devices.

Land attended Harvard University briefly in 1926 but left to pursue research in the field of polarizing optics. The technology he developed, the first inexpensive light-polarizing filter, was initially used in sunglasses and scientific work but was eventually utilized in color animation, camera filters, 3-D movie

Edwin Land, cofounder of Polaroid Corporation, revolutionized in-camera instant photography when he invented inexpensive filters for polarizing light. His Polaroid instant camera made it possible for consumers to take and develop their own pictures. (Fritz Goro/The LIFE Picture Collection/Getty Images)

glasses, and tinted windows. He applied for his first patent for polarizing sheets in 1929, and in 1932, he, along with Harvard colleague George W. Wheelwright, established Land-Wheelwright Laboratories in Cambridge, Massachusetts, to produce applications using this polarizing technology. In 1937, the company became known as the Polaroid Corporation.

During World War II, Land's company worked extensively with the U.S. military, producing optical equipment such as cameras, viewfinders, antiglare goggles, and gun sights. A previous invention, the Vectograph, assisted the war effort by giving a three-dimensional perspective of battlegrounds and aerial maps, enabling the military to perceive camouflaged enemy positions.

Land's most famous invention, the Polaroid camera, was prompted by his three-year-old daughter's dismay that photographs taken with conventional cameras could not be viewed immediately. He began the development process in 1943 and was ready to demonstrate his revolutionary instant photography

technology in 1947. When the first Polaroid cameras went on sale in 1948, all were sold within the first day. These first Polaroid images were sepia toned, and in 1950, the company achieved black-and-white capabilities. By 1963, Land had developed an instant color camera, and in 1972, he developed the iconic SX-70, the first truly one-step instant camera. (Previous versions had required steps such as treating the image with a coating.) It is estimated that during this era, more than half of U.S. households owned Polaroid cameras. In 1978, Land developed an instant color movie-making system, but it was not a commercially successful product.

During the Cold War era, Land served as science advisor to the federal government, assisting in the development of cameras for the U-2 spy plane and the Corona satellites. After his retirement in 1982, Land continued his scientific research, creating and financing the Rowland Institute for Science in Cambridge, Massachusetts. During this time, he developed laser technology capable of manipulating microscopic organisms such as bacteria, and he proposed the retinex theory of color vision perception.

Ansel Adams, a celebrated American landscape photographer, called Polaroid film “superior” and served as a prominent collaborator in the development of Polaroid films. Steve Jobs, cofounder of Apple Inc., credited Land with being a significant influence on his approach to invention and design. Land was awarded the Medals of Freedom (1963), Science (1967), and Technology (1988). During his lifetime, Land was granted 535 patents, second only to Thomas Edison.

Lasers

“Light amplification by stimulated emission of radiation,” more commonly known as “laser,” has created revolutionary changes in American life in fields from science to medicine to the environment, and to technical and operational fields. Lasers have changed how we watch a movie, save lives, and expand our knowledge about our world and new worlds. Theodore H. Maiman, working for Hughes Research Laboratories, invented the laser in 1960, in concert with Charles H. Townes and Arthur L. Schawlow.

Laser light is created when electrons are excited by an electrical current. They move to a higher-energy state in atoms, and when they return to their normal state, they emit particles of light called “photons.” Lasers are devices that transmit intense light in nice, parallel wavelengths. Although the light from different lasers can be different colors, the light emitted from each laser is monochromatic, which means each is only one color. Also, unlike natural light, which tends to disperse, lasers light travels in the same direction and concentrates its intense light in only one spot at longer distances than natural light. Lasers are made from different materials, like gas, glass, polymers, and crystals.

In 1917 Albert Einstein (1879–1955) first proposed the stimulated emissions theory, which was about how atoms can go back to a state of equilibrium after being stimulated. Charles Towne developed a microwave amplifier that functioned with the same principles as a laser. This “maser” could not sustain continuous light output at first. Scientists, including Neils Bohr, argued that Towne’s maser could not exist because it violated Heisenberg’s uncertainty principle. Nonetheless, in 1964, Townes shared the Nobel Prize in Physics for his work on masers.

In 1960, Theodore Maiman was the first physicist to construct a laser with a cylinder of synthetic ruby. He created it at the Hughes Research Laboratory, and his work was based on the theories of Einstein, Charles Townes, and Arthur Schawlow. That same year, the first beam light laser was also created, reaching the distance of 1.15 μm .

In 1961, the laser made its first appearance on television in an advertisement. In October of that year, the

first neodymium glass laser was created, which was a better-resolution laser. It had higher uniformity and concentration than common lasers at that time. Later, a revolutionary event changed everything in the medical field. In December 1961, the first medical treatment with lasers on a human being was performed. This led to discoveries that not only helped people to heal but also enhanced human beauty. However, it was not until 1963 that the first cardiovascular surgery was performed by using a ruby laser. The surgery was done by a Dr. McGuff relating to the ablation of atherosclerotic plaques.

In 1962, the gallium arsenide laser, a semiconductor device was created. This device converted electrical energy into infrared light. However, the most commonly used laser today in homes and industry are diode lasers or LDs, which are semiconductor lasers. In 1978, the laser made the world of CDs and DVDs possible. In 2009, NASA sent the first lunar-orbiting laser to scout safe landing sites, measure lunar radiation, and identify potential moon resources.

New types of lasers are built everyday with new purposes and new potentials. Lasers have redefined our way of life, even modifying how we look with little effort. They save lives, making surgeries easier than before and less time-consuming.

Today, lasers are essential tools in the transformation of materials, like cutting or welding them, or in the production of new objects. They are also very useful in communication and the reading of information, as in supermarket scanners, TV and car remotes, or CDs, DVDs, and Blu-ray players. Lasers are also used by dermatologists and in other medical fields for human enhancement surgery—to correct vision, save lives, heal, and get rid of unwanted traits.

Lasers have also been used by NASA to create two-way communication. It aims to replace radio waves with what is known as “optical payload for laser comm science,” or OPALS. NASA has already sent information from the moon base to Earth with LLCD, which stands for “Lunar Laser Communication Demonstration,” but it was only one-way information. If OPALS becomes possible, two-way communication will increase resolution, and one day, we will be able to transmit three-dimensional videos via laser.

LED Lights

A light-emitting diode (LED) is a two-lead semiconductor that operates as a light source. It is commonly designed using a p-n junction diode that emits light when connected with an energy source. When a voltage is applied to the leads, electrons combine with electron holes in the device, releasing photons as energy. This process is called “electroluminescence,” where the color of the light is effected by the energy band gap of the semiconductor that it has been powered by. LED lights are small most of the time, usually below 1 square millimeter, and they are widely used as integrated optical components in electronic devices.

LED lightbulbs have gained considerable consumer popularity in the 21st century, although they are more expensive than traditional lightbulbs. They last longer and are significantly more energy efficient.

Liquefied Natural Gas (LNG) Carrier

A liquefied natural gas (LNG) carrier is a type of ship used to transport natural gas in large quantities where pipelines are impracticable. The first ocean LNG carrier was the *Methane Pioneer*, first built by the United States in 1958. It shipped off from the Louisiana Gulf to Canvey Island in the United Kingdom. Since then, LNG carriers have improved their capacity and capabilities, including more efficient regasification processes. The natural gas cargo is cooled down to -160°C at atmospheric pressure, where it significantly reduces the volume used by 600:1, making large quantities of natural gas efficient to transport.

LNG carriers are a valuable transportation tool. Since an increase in emerging markets in developing countries leads to a higher demand for energy, LNG carriers offer a simple and fast solution to the immediate need for fuel. These carriers are used to transport natural gas to supply poor areas, allowing such nations a stable source of fuel throughout the year. This transportation method makes resources from remote and deep ocean areas accessible to people around the world where pipelines cannot reach or cannot be placed fast enough.

The tanks are initially gas free because the cargo cannot be loaded with oxygen present, since the two elements would react and explode. An inert gas plant burns diesel in the air to produce a mix of oxygen, carbon dioxide, and nitrogen. This gas mix is blown into the tanks until oxygen levels are below 4 percent. Impurities in natural gas like sulfur and carbon dioxide are removed prior to loading it. The next step is to gas up and cool down the cargo; the tank is warmed to 68°C, and inert gas is blown in to remove any carbon dioxide present until it reaches 5 percent of volume. The tank is next filled with methane, and the gas is placed in a cargo containment system that cools the gas to -160°C, when it is placed in a high-pressure tank. Once cooled, it remains at atmospheric pressure with no significant changes. The LNG does have some drawbacks, since its cargo can evaporate away, losing 0.10 to 0.15 percent of volume per day. This is known as boil-off gas.

The United States is an energy-rich nation with vast natural gas reserves, so these carriers offer a way for it to expand its exports. With a higher demand, the

vessels are being redesigned to incorporate increased cargo capacity, more efficient systems, insulation, and liquefaction and regasification systems. In 2017, Russia created the world's first icebreaking LNG carrier capable of going through ice that is 2.1 meters thick, allowing more resources in the Arctic Circle to be accessible. Now, natural gas in the Arctic can be accessible year-round.

Liskov, Barbara (1939–)

Barbara Liskov is recognized for being one of the first women to be granted a doctorate in computer science in the United States. In 2008, she won a Turing award for developing the Liskov Substitution Principle. Her contributions to programming language design and software methodology led to the development of object-oriented programming, a language structure that is used by virtually every coding platform today.

Barbara Jane Huberman was born on November 7, 1939, in Los Angeles, California, and was the eldest of Jane Dickhoff and Moses Huberman's four children. In 1970, she married Nathan Liskov, and by 1975 had had her first son, Moses Liskov. She earned her bachelor's degree in mathematics from the University of California, Berkeley in 1961. Liskov then worked as a programmer with the MITRE Corporation for about a year but left to work at Harvard University on language translation. In 1963, she returned to California to work with John McCarthy on some of his artificial intelligence projects at Stanford University. In 1965, Liskov earned a master's degree and then a doctorate in 1968 from Stanford, becoming the first woman in the United States to have a doctoral degree in computer science.

After receiving her doctorate, she returned to the Boston area to continue working at MITRE on

computer design and operating systems. It was there that she created the Venus computer, which used an operating system that was tailored for the creation of complex software. Liskov then returned to MIT that same year and joined the faculty as a professor in the Laboratory for Computer Science. While at MIT, she led a group that created the Argus language and developed the Liskov Substitution Principle.

In 2004, Barbara Liskov was awarded the John von Neumann Medal for her “fundamental contributions to programming methodology, and distributed systems.” In 2005, she was awarded an ETH Honorary Doctorate from the Swiss Federal Institute of Technology in Zurich, and in 2008, she received the 2008 Turing Award from the Association of Computing Machinery for her contributions to the design of programming languages and software methodology that led to the development of object-oriented programming. Liskov leads the Programming Methodology Group at MIT with a current focus on Byzantine fault tolerance and distributed computing. In 2012, she was inducted into the National Inventors Hall of Fame.

Liskov is currently an institute professor, the highest honor awarded to an MIT faculty member, and is Ford Professor of Engineering in the School of Engineering’s electrical engineering and computer science department.

M16 Rifle

The M16 has been called one of the technological success stories of the 20th century. A lightweight, select-fire weapon with a high-capacity magazine, the M16

seemed to be the answer to combating America’s Cold War enemies. But before and even after it went into use in the mid-1960s, its principal adversaries were its patrons and its users.

Actually, the M16 was the army’s name for the AR-15, a high-velocity, semiautomatic or fully automatic rifle built by the Armalite Corporation in the 1960s. It wasn’t the army’s first choice. It had been on the hunt for a new infantry weapon since the end of World War II. Engagements with fanatical enemies had convinced it that a weapon firing a cartridge with more stopping power had to be developed. That led to the adoption of the M14, but while it certainly had the stopping power, thanks to a 7.62 mm slug, it was heavy and its recoil made the weapon inaccurate. It also didn’t feature a large-capacity magazine to keep the M14 in action. So, the search went on for something new and different.

Eugene Stoner, an Armalite engineer, had just that in mind when he developed the AR-15. It was different in every way. For starters, it wasn’t built like most weapons, which involved the machining and casting of metal parts. The AR-15’s pieces were stamped, pressed and forged, and equipped with a plastic stock in place of the traditional wooden one. The inside of the AR-15 was just as innovative. The piston assembly used to make the weapon work was gone; in its place was a simple tube that fed gas into the bolt carrier, which propelled shells out of the barrel. And coming out of that barrel was a 5.56 mm slug fed from a high-capacity magazine. Smaller than the 7.62 mm round and less lethal than the .30-caliber slug, the AR-15’s ammo proved it could meet the army’s expectations. It could penetrate a U.S. Army helmet at 500 yards, retain a velocity in excess of the speed of sound, and match or exceed the wounding ability of the .30-caliber cartridge. In addition, the AR-15 weighed less than seven pounds, which in the view of the U.S. Army’s Infantry Board made it an ideal weapon for the fully loaded, and sometimes overloaded, GI to carry.

While the Infantry Board was willing to sign off on the AR-15 and rechristen it the M16, the Ordnance Board, another department within the army, didn’t think the weapon was accurate enough. It produced studies that showed that once fired, the small 5.56 mm shell immediately began to lose speed and stopping power, and its trajectory could be easily diverted by

leaves or even sticks on the way to a target. Since the number of hits was more important to the Ordnance Board than the number of shots fired, it came out against the M16. Further complicating matters was the fact that American forces, along with troops belonging to the North Atlantic Treaty Organization (NATO), had sought to standardize weapons and equipment and had earlier settled on the 7.62 mm round. Any deviation from that policy could cause severe disruptions within the alliance. Accuracy and continuity carried the day, and the army rejected the M16.

The debate over the use of the M16 continued until 1967, when the controversy landed on the desk of Defense Secretary Robert McNamara. Other service branches had adopted the weapon, including the army's own Special Forces, for use in Vietnam. That unit concluded that the M16 was superior for the type of operations it was conducting. Success in jungle warfare depended less on accuracy and more on firepower. The M16 was easy to carry and just as easy to bring into action. Plus, with its high-capacity magazine and full-auto feature, a soldier could spray a target, reasonably sure he had hit it, and be confident he would live to talk about it. But that's not to say the M16 didn't still have problems. The gas-operated, pistonless system that made the M16 so light occasionally caused the weapon to jam during use. Jamming also occurred when users taped clips of bullets together to allow for a more rapid rate of fire. Sometimes one of the clips got hung up in the feed mechanism and caused a malfunction.

With the Special Forces data in hand, and taking the operational liabilities into consideration, McNamara ordered the M16's purchase by the U.S. Army. It was bad news for NATO, as its 7.62 mm cartridge wouldn't fit into a weapon destined to become the most widely used in the world. It was also bad news for Eugene Stoner and the Armalite Corporation, as the contract to mass-produce the M16 was awarded to Colt Industries.

John A. Morello

Magnetic Resonance Imaging (MRI)

Magnetic resonance imaging (MRI) is a technique used for medical purposes to form images of the body. It uses magnetic fields and pulses of microwave energy to create images of the organs of the patient. The first MRI was created in 1970 by Raymond Damadian, who discovered that each organ emits a different resonance wave due to a difference in water content. This was the foundation for the MRI to be able to image individual tissues and organs. It has been in use in hospitals since 1980.

This method gives medical personnel additional information about the patient, such as the movement and presence of disease, not just the structural image provided by an x-ray. It is a landmark medical technique since it is a noninvasive procedure used to diagnose diseases. In some cases, an MRI can be used to detect cancer since cancer cells emit a different hydrogen NMR signal than healthy cells because cancer cells contain more water. MRIs are used to find various problems such as tumors, internal bleeding, and multiple sclerosis.

The medical uses of MRIs are wide due to the composition of the human body being two-thirds water, which contains hydrogen atoms. When the human body is exposed to a strong magnetic field, the nuclei of the hydrogen atoms orient themselves in a certain direction. Pulses of radio waves are then emitted at the body, causing the hydrogen to emit a resonance wave. This wave causes a difference in the oscillation of the nuclei, which is detected and processed to create the image of an organ.

Since its original use in full-body scans, more specialized applications of MRIs have been invented, such as diffusion MRI and magnetic resonance angiography (MRA). Diffusion MRI measures the diffusion or random motion of water within tissue. This gives a better understanding of the structure of organs, since it often reflects interaction with many neighboring areas. It is used for neuroimaging and is commonly used to determine if a patient has had an acute stroke or a neurological disorder. MRA focuses on imaging blood vessels, generating images of arteries to analyze them for any present disease or blood flow issues. This technique is most commonly used to image blood vessels in the legs, kidneys, and brain. The image

generated provides information on the blood flow and the current state of the blood vessel walls. It offers an alternative to traditional angiography, which involves inserting a catheter into the body. MRA is an alternative, noninvasive procedure.

MASER

A MASER, or “microwave amplification by stimulated emission of radiation,” is a device that emits a self-sustaining stream of microwave radiation by directing microwaves through free electrons. The original MASERS were invented to study the structure of molecules, atoms, and atomic nuclei. After World War II, attempts were made to reconfigure radar devices to study the smallest building blocks of matter, but no one was able to produce electromagnetic radiation less than one centimeter in wavelength. The breakthrough occurred when pioneering physicist Charles H. Townes configured an apparatus that utilized microwave radiation to excite molecules of ammonia gas in a resonant cavity, which then chain reacted as the excited molecules emitted radiation—which then further promoted radiation emission. The feedback between the excited molecules and the microwaves exciting them created a steady, self-sustaining stream of amplified microwaves. The original device’s total power was around 10 nanowatts and over one centimeter in wavelength, but the energy emission was uniform in wavelength, which had never been accomplished before.

The MASER’s inventor, Charles H. Townes, was born July 28, 1915, in Greenville, South Carolina. He

received his PhD in physics at the California Institute of Technology, and then he worked on the technical staff of Bell Telephone Laboratories, designing radar systems during and after World War II. His first functioning MASER was tested successfully in 1954 while he worked at Bell Labs, but skepticism persisted that there were any practical applications for the device. Four years later, he and Arthur Schawlow, Townes’s fellow physicist and brother-in-law, demonstrated how the principle of the MASER could be applied to both infrared and optical electromagnetic frequencies. Their proposal for a LASER (“light amplification by stimulated emission of radiation”) was patented in 1960, and in 1964, he received the Nobel Prize in Physics for his work relating to optical physics and quantum electrodynamics, which he shared with Nikolay Basov and Aleksander Prokhorov. Townes and his assistants were also the first to detect complex molecules in space and to provide the first measurements of the Galactic Center. Townes died on January 7, 2015 at age 99.

Arthur L. Schawlow, a pioneer in MASER technology alongside Townes, was born on May 5, 1921, in Mount Vernon, New York. He received his graduate degree at the University of Toronto and then studied under Townes—considered a leader in the field of microwave spectroscopy—at Columbia University. While there, he married Townes’s younger sister, Aurelia, transferring to Bell Labs to study superconductivity to avoid Columbia’s antinepotism policies. The year after he and Townes patented the LASER, he joined Stanford’s Physics Department. He was still associated with Stanford when he shared the 1981 Nobel Prize in Physics with Nicolaas Bloembergen and Kai M. Siegbahn for “their contribution to the development of laser spectroscopy.” Schawlow died on April 28, 1999, in Palo Alto, California.

McClintock, Barbara (1902–1992)

Cytogeneticist Barbara McClintock was the first woman to win an unshared Nobel Prize. By studying heredity and, more specifically, genes, she proved that genetic elements can sometimes change position on a chromosome and that this causes nearby genes to become active or inactive.

Barbara McClintock was born on June 16, 1902, in Hartford, Connecticut, to Sara Handy McClintock and Thomas Henry McClintock. Her parents first named her Eleanor but changed her name to Barbara after deciding that Eleanor was too delicate a name for their sturdy daughter. McClintock's father was a family doctor, the child of immigrants from Britain, and her mother was from an upper-class family from Boston, with a career in poetry and art. Barbara McClintock had two older sisters, Marjorie and Mignon, and a younger brother, Malcolm.

In 1908, the McClintock family moved to Brooklyn, where McClintock graduated high school in 1919. While in high school, McClintock discovered her love of science. McClintock's mother did not want her daughter to attend college, because she believed it would make her daughter unmarriedable. Luckily, McClintock's father intervened. In 1919, she began classes at Cornell.

Barbara McClintock took her first course in genetics in 1921, the only course in genetics open to undergraduate students at the time. Naturally gifted in the subject, she caught the attention of Claude B. Hutchison, professor in the Department of Plant Breeding, College of Agriculture, who promptly recommended that she attend a graduate-level course as soon as possible—the only other genetics course given at the university.

In the 1920s, genetics was not a generally accepted discipline. Only a couple of decades had passed between then and the rediscovery of Mendel's principles of heredity. Regardless, McClintock devoted her studies to genetics, specifically plant genetics. After graduating with a bachelor of science degree in 1923, she earned a master's and then in 1927 a PhD in botany, all from Cornell University.

McClintock won a Guggenheim scholarship that allowed her to study in Germany in 1933 and 1934. She had planned to work with prominent geneticist

Curt Stern, but when he fled Nazi Germany for the United States, she studied with Richard Goldschmidt. Rising anti-Semitism and war sentiment in Germany made McClintock uneasy, so she returned to the United States. Cornell next offered McClintock a position as instructor in the Botany Department. Along with teaching, she also researched plant genetics. While at Cornell, she won a two-year Rockefeller Foundation grant.

In 1941, McClintock became an assistant professor at the University of Missouri and, in the same year, a visiting professor at Columbia University. In 1944, McClintock began studying the relationship between patterns on corn plants and their chromosomes, focusing primarily on purple-spotted corn.

During the 1940s and 1950s, McClintock discovered that genes are responsible for determining physical characteristics, and she proved that they used transposition to change characteristics from one generation to another. The next year, she presented her work at Cold Spring Harbor's annual summer symposium. One colleague said that she had done more to uncover the genetic structure of a particular mold fungus than all the scientists that had studied the organism before. In 1944, she returned to her study of maize genetics. Her findings in gene transposition in the 1940s and 1950s fundamentally changed the study of genetics and chromosome mechanisms. As her work continued to break ground, some scientists took issue with her findings. In 1953, she took a hiatus from publishing, hoping that other geneticists would eventually catch up to her work.

In 1957, McClintock won yet another grant, this one from the National Science Foundation, to study indigenous maize in South America. McClintock relished the opportunity to undertake a study in evolutionary biology that would fundamentally change paleobotanists' understanding of plant evolution.

McClintock did not go without recognition. In 1983, she became the first woman to receive an unshared Nobel Prize in Physiology or Medicine. She was 81 years old. She was also awarded membership in the National Academy of Sciences, gaining the presidency of the Genetics Society for a time, the National Medal of Science from President Richard Nixon, the very first MacArthur Laureate Award, and more.

Geneticist Barbara McClintock won the 1983 Nobel Prize in Medicine for her work on genetic recombination by crossing over. Scientists recognize her as one of America's most significant scientists. (Barbara McClintock Papers, American Philosophical Society)

She died on September 2, 1992, at the age of 90 from natural causes at Huntington Hospital in Huntington, New York. Dr. Barbara McClintock died peacefully, her mind remaining sharp and methodical in her research until her time of death.

Though her work was largely forgotten for decades, interest in women in science in the late 20th and early 21st centuries led to McClintock's rediscovery. Biographies about McClintock make it clear that much of the difficulty she encountered in her life as a scientist had stemmed from the fact that she was a woman. In 2005, the U.S. Post Office issued a Barbara McClintock stamp.

Mercury 13

The “Mercury 13” is a nickname for the group of women who successfully completed the first phase of NASA’s physical and psychological testing to qualify as astronauts. Most of these women were accomplished pilots aspiring to be the first female astronauts. In 1960, Geraldyn “Jerrie” Cobb was the first to pass all three phases of the test. Altogether, 20 women were invited to complete the first phase of astronaut testing, and 13 passed. They became known as the “First Lady Astronaut Trainees” or FLAT, and later in 1995, the term “Mercury 13” for them was coined by Hollywood producer James Cross.

The women in the Mercury 13, or FLAT, were: Jerrie Cobb, Wally Funk, Irene Leverton, Myrtle “K” Cagle, Janey Hart, Gene Nora Stumbough (Jessen), Jerri Sloan (Truhill), Rhea Hurrle (Woltman), Sarah Gorelick (Ratley), Bernice “B” Trimble Steadman, Jan Dietrich, Marion Dietrich, and Jean Hixson.

The tests administered to these women were privately funded as part of Project Mercury and not officially through NASA. Project Mercury was started by William Randolph Lovelace II, chairman of the NASA Special Advisory Committee on Life Science. Lovelace was influential in creating the tests undergone by male NASA astronaut candidates and was curious about how women would perform on the tests.

Phases II and III of this testing were never administered to the women. The military halted the use of their equipment until Lovelace had an official order from NASA to continue testing. Since Project Mercury was privately funded and not an official project of NASA, Lovelace was not able to gain NASA’s approval, so the Mercury 13 were unable to continue testing. These women were not part of NASA’s astronaut program and never flew in space, even though they did the same tests as the male astronauts. The male astronauts later became known as the “Mercury 7.” The Mercury 7 included: Alan Shepard, Gus Grissom, John Glenn, Scott Carpenter, Wally Schirra, Gordon Cooper, and Deke Slayton.

The women of the Mercury 13 never officially became NASA astronauts, but they were accomplished, attained honors, and had overall successful

lives. The initial woman to undergo these tests, Jerrie Cobb, was inducted into the National Aviation Hall of Fame on October 6, 2012. As a group, Jerrie Cobb, Jerri Truhill, “B” Steadman, Rhea Woltman, Sarah Ratley, Gene Nora Jesson, Irene Leverton, and Myrtle “K” Cagle were awarded with honorary doctor of science degrees from the University of Wisconsin-Oshkosh on May 12, 2007.

Military-Industrial Complex

The phrase “military-industrial complex” (MIC), which refers to close ties between the American military leadership and the American defense industry, was first coined by President Dwight D. Eisenhower in his televised farewell address in 1961. Although the American military and businesses had cooperated during previous wars, Eisenhower believed that Cold War (1945–1989) fears would lead to the MIC’s “unwarranted influence.” He warned, “The potential for the disastrous rise of misplaced power exists and will persist.” Therefore, he asked Americans to be vigilant, and he proposed two solutions for the problem. First, he recommended scaling back the size of the military during times of peace. Second, he believed that an investment in new weapon technologies would give the United States an edge over other nations.

Throughout the 1960s and 1970s, critics of the Vietnam conflict (1955–1975) routinely referred to the MIC as a root cause of American involvement. And, as the war dragged on year after year, Eisenhower’s

warning seemed prophetic. By the 1980s, references to the MIC declined even though the U.S. defense budget skyrocketed during President Ronald Reagan's administration (1981–1989). After the Cold War, presidents found it difficult to secure popular support for maintaining a wartime-size military during peacetime.

Eisenhower, a former general who commanded the troops during the D-Day invasion that had liberated France from the Germans (1944), was not soft on the issue of defense. He believed that a strong military was important. However, he objected to wasteful military spending due to military contractors who padded bills. Eisenhower was not the only leader with this concern. Eight years before his speech, the U.S. Congress launched an investigation of deals made by military leaders and contractors. According to the report, \$1 million had been spent on “unnecessary” chain-link fences for the Air Force, \$3 million on “useless” navy forklifts, and \$45 million on “unsuitable” army overcoats. Led by Representative R. Walter Riehlman (a New York Republican), Congress deemed the spending “costly and wasteful.” In spite of the report, government defense spending continued to rise unabated. By the time of Eisenhower's speech, defense spending stood at \$46.4 billion (a 38 percent increase since 1949).

Certainly, the phenomenon of cooperation between the military and civilian businesses was not new. In the 1880s, the United States set about building a new navy. The massive undertaking required cooperation between political leaders, naval officers, and industrialists. The huge sums of money exchanged between the government and private businesses funded the creation of the “Great White Fleet,” which Theodore Roosevelt proudly showed off to the world (in a world tour) during his presidency.

During World War I (1914–1918), the War Industries Board (WIB), a group of military leaders and private industrialists, coordinated to supply American troops. At the direction of the WIB, factories went from producing consumer goods (including automobiles, home radios, and home appliances) to producing military materials (including airplanes, military radios, and rifles). During World War II (1939–1945), the War Production Board (WPD) had a similar makeup and function as the WIB. However, the WPD managed a

much larger operation, because World War II was the largest war to date.

Throughout American history, the United States had followed the same cycle of mobilization (with a large military budget) during war and demobilization (with a reduced military budget) during peacetime. Initially, the country followed the same pattern at the conclusion of World War II. However, the deterioration of U.S.–Soviet relations after World War II resulted in the two nations becoming enemies. In 1949, four years after the war, the Soviets tested their first atomic bomb. The worsening relations and the fact that the Soviets were perceived as a threat reversed American demobilization.

President Harry S Truman (1945–1953) pushed for the creation of the first hydrogen bomb, which was much more powerful than the atomic bombs that the United States had dropped on Japan during World War II. Looking for an alternative to nuclear warfare, Americans and Soviets entered into an arms race as they built up their storehouses of conventional weapons. An important feature of the Cold War tied to the use of conventional weapons was the policy of containment. Just like dominoes in a row, Eisenhower and others argued that if one nation fell to communism, bordering nations would also fall. Beginning with Truman, all Cold War-era U.S. presidents practiced their own particular policies of containment. For example, the United States (with help from the United Nations) prevented the spread of communist ideology during the Korean conflict (1950–1953) and Vietnam conflict (1955–1975).

By 1957, the Cold War included both an arms race and a space race. That year, the Soviets launched Sputnik I, the first man-made object to orbit the earth. Americans reacted in several ways to the Soviet display of its new technology. Politicians blamed American technological inferiority on a failure of the American educational system. In 1958, Congress passed the National Defense Act, which provided millions of dollars to public schools for their science and foreign language programs.

That same year, Congress budgeted for the establishment of the National Aeronautics and Space Administration (NASA) to help the United States catch up and win the Space Race. Some military leaders voiced concern over what they called the “missile gap.” In other words, Sputnik technology had made it possible for

Soviets to place a nuclear warhead on a missile that could then orbit the earth and destroy targets from vast distances. The Soviet technology left the United States at a tremendous disadvantage in 1957. Some Americans reacted to Cold War fears by building bomb shelters in their backyards. Schools held atomic bomb drills in which they had children hide under tables and desks in preparation for a possible Soviet attack. These Cold War fears and attitudes threatened to expand the American military beyond any previous peacetime limits.

By the 1950s, several major U.S. corporations were entirely dependent on military contracts. In addition, U.S. corporations became one of the world's leading exporters of conventional weapons. In fact, the huge profits from arms sales were a major factor in American economic growth. Eisenhower pointed out that when military and political leaders were corporate stockholders (who stood to benefit from profits), their endorsement of certain military decisions should be scrutinized to ensure that greed and the desire for personal gain did not compromise national interests. During the Vietnam conflict, for example, more conventional bombs were dropped by the United States on North Vietnam than all of the conventional bombs dropped by all of the warring nations during World War II. Throughout the long Vietnam conflict, military suppliers made great profits.

Eisenhower proposed a solution to the threat of a ballooning military establishment. He recommended a reduction in troop numbers and an increased emphasis on development and dependence on sophisticated technologies. Surely, the development of incrementally more powerful bombs during the Cold War was an example of this kind of strategy. Perhaps the most striking example of a reliance on new military technologies was President Ronald Reagan's plan for the trillion-dollar Strategic Defense Initiative ("Star Wars"). The purpose of "Star Wars" technology was to deploy a satellite laser network over the earth to protect the United States against an incoming nuclear attack. Unfortunately, after spending \$70 billion on research and laboratory tests, scientists were unable to build a functional Star Wars network.

Reagan believed that the best way to defeat the Soviets was by outspending them. He increased defense spending to build more ships, tanks, airplanes, and nuclear weapons. He pushed for government grants for

research institutions working on advanced weaponry. In fact, defense spending ate up so much of the budget that it led to funding cuts in many social programs, including food stamps, Medicare, education, and Social Security. Occasional critics of the massive defense budget pointed to government records that documented highly overpriced military hammers and toilet seats. Some explained the high prices by accusing the MIC of abuses. Others speculated that secret projects might have been funded by the padded bills. In general, critics charged the Reagan administration with the development of expensive yet malfunctioning weapons and a tremendous waste of the budget.

After the Cold War, President Bill Clinton (1993–2001) greatly reduced the size of the military, and he continued to rely on innovations in technology to remain a military leader in the world. President George W. Bush (2001–2009) built a land-based missile defense system nicknamed "Son of Star Wars." The combined cost of both the failed Star Wars project and its land-based descendant was approximately \$100 billion.

Minsky, Marvin (1927–2016)

Marvin Minsky was an American scientist who was part of a group of scientists and mathematicians considered to be the founding fathers of artificial intelligence (AI). Minsky and his work in AI led him to cofound the Massachusetts Institute of Technology

Artificial Intelligence Laboratory now known as the Computer Science and Artificial Intelligence Laboratory. The lab was responsible for building and developing robots and creating revolutionary programs. Minsky also published several books on artificial intelligence as well as philosophical analyses. He is the recipient of the ACM A. M. Turing Award, which is thought of as the Nobel Prize of computing, along with several others over the years of his work.

Minsky was born in New York City in August 1927. For his early education, he attended the Ethical Culture Fieldston School, followed by the Bronx High School of Science, and finally Phillips Academy. Next, he was off serving in the U.S. Navy during World War II. In 1950, he earned his bachelor's degree in mathematics from Harvard University in Cambridge, Massachusetts. In 1954, he received his PhD from Princeton University, building the first randomly wired neural network learning machine.

After receiving his PhD, he was recommended as junior fellow at Harvard. In 1958, he began teaching at MIT, and Minsky, along with John McCarthy, founded the Artificial Intelligence Laboratory there, where it built pioneering robots. In the lab, they worked on ways to influence the human psychological process through AI and attempted to create machines to imitate human perception and intelligence. They also created practical robots. Minsky accurately predicted that microsurgery could be done by a surgeon at one end of a telepresence system with adjustable scale and focus, with a machine on the other end doing the hands-on, small-scale part of the skilled work.

In a foreshadowing of microsurgery, he created the first robot with mechanical hands and tactile sensors. Minsky also argued that space exploration and nuclear material processing would be simpler using machines driven locally by computers and remotely by humans.

In the 1960s, he worked with mathematician Seymour Papert to develop better neurally inspired mechanisms. They wrote *Perceptrons*, which analyzed artificial neural networks and their abilities. In the 1970s and 1980s, they developed theories of intelligence and radical approaches to children's education through an educational programming language called Logo.

During the mid-1970s, Minsky developed the theory of frames, a way of describing entities and situations using a template-like representation. In 1980 he

published *K-Lines: A Theory of Memory*, a journal article that described the group of “mental agents” that activate when a human solves a problem or has a new idea. These and many other ideas of his came together in Minsky's 1986 book *The Society of Mind*. He wrote that intelligence may come from behavioral factors that are undoubtedly nonintelligent. In 2006, he published *The Emotion Machine*, which elaborated on the ideas in *The Society of Mind* and reviewed scientific progress on artificial intelligence.

Minsky earned many awards, including the fourth-ever ACM A. M. Turing Award in 1969 for his role in AI. In 1990, he received the Japan Prize, followed by the International Joint Conference on Artificial Intelligence Award for Research Excellence in 1991. In 2001, he was awarded the Benjamin Franklin Medal. In 2006, he earned a place in the Computer History Museum and in 2011 in *Intelligent Systems* magazine's AI's Hall of Fame. Finally, in 2014, he won the Dan David Prize for the field of Artificial Intelligence, the Digital Mind. His last position was Toshiba Professor of Media Arts and Sciences and professor of electrical engineering and computer sciences at the Computer Science and Artificial Intelligence Laboratory. The founding father of AI passed away at the age of 88 on January 24, 2016.

Moog, Robert (1934–2005)

Robert Arthur “Bob” Moog was born May 23, 1934, in Queens, New York. He is the founder of Moog Music Inc. He is known as an engineer and the founding father of electronic music. He also invented the Moog synthesizer.

Moog attended the Bronx High School of Science in New York and graduated in 1952. He then attended Queens College and earned a bachelor's degree in physics. He later earned a bachelor's degree in electrical engineering from Columbia University. For his PhD in 1965, he studied engineering physics at Cornell University. When he was 20 years old, Moog and his father had begun to build theremins—electronic musical instruments controlled without physical contact. In them, two metal antennae produce a magnetic field, and one waves one's hands in the field to control the volume and the pitch. Inspired by his father, Moog fell in love with electronic music.

In 1961, Moog made a living selling theremin kits at \$50 apiece. Also in that year, he wrote an article about them for *Electronic World*, an electronics magazine, and he received about 4,000 orders for more theremins, which he built in this three-room apartment. About two years later, Moog was inspired by composer Herbert A. Deutsch, to construct the first Moog modular synthesizer composed of two voltage-controlled oscillators, two voltage-controlled amplifiers, and a controller that could turn the sounds on and off and change the pitch and rates of modulation.

The following year, Moog brought his hand-made Moog modular prototypes to the Audio Engineering Society convention to demonstrate it. He took orders for it there, and his business grew. In 1967, he incorporated R. A. Moog Company, now called R. A. Moog Inc., and began the introduction of Moog modular Synthesizers I, II, and III.

Moog himself did not play music, but in the following year, his company released Wendy Carlos's *Switched-On Bach* album, an entire album recorded with a custom-made Moog modular synthesizer. In 1970, Bill Waytena purchased the company and soon released different models of "Minimoog," and the company was relocated to Buffalo, New York, in 1971. In 1977, Moog left the company to serve as vice president of new product research at Kurzweil Music Systems, where he stayed until 1989. After that, he rediscovered his interest in theremins and designed the series 91 theremin in 1996.

During the 1970s, less expensive digital synthesizers came to the market. Moog's company did not have the right to produce this kind of synthesizer, and

that led his company to bankruptcy. He sold the rights to his company and in 1978 moved to Asheville, North Carolina, to set up the Big Briar music company, building theremins and analog synthesizers. In the meantime, the Moog synthesizer continued to gain popularity in the 1980s; most musicians preferred it for its "warmer" sound over that of less expensive brands.

In April 2005, Robert Moog was diagnosed with inoperable brain cancer. On August 21, 2005, he passed away at his home in Asheville. Afterward, the Bob Moog Foundation was created with the aim of continuing his work developing electronic music.

Morgan, Mary Sherman (1921–2004)

Mary Sherman Morgan was the first female rocket fuel scientist in the United States. She invented Hydyne liquid fuel, which powered the Jupiter-C rocket. Though in use only for a limited time, Hydyne fuel was responsible for launching the rockets that placed the United States' first satellite, Explorer I, into space.

Born on November 4, 1921, on a farm in North Dakota, Morgan graduated as valedictorian of her high school in 1939. She enrolled at North Dakota's Minot State University to study chemistry. While she was there, World War II broke out. She dropped out of college and went to work for the Plum Brook Ordnance Works munitions factory in Sandusky, Ohio, for which she needed top security clearance. She was part of the

team that manufactured explosives such as trinitrotoluene (TNT), dinitrotoluene (DNT), and pentolite.

After the war ended, Morgan took a job with North American Aviation's Rocketdyne Division in Canoga Park, California, and was soon promoted to theoretical performance specialist, calculating the expected performance of new rocket propellants. She was the only woman on a team of 900 engineers and one of only a few without a college degree.

North American Aviation was awarded a contract to develop more powerful fuel for the Jupiter missile program. Morgan worked with a group under the direction of Dr. Jacob Silverman at the Rocketdyne Division and was named technical lead on the contract. Her work resulted in a new propellant, Hydyne, which was used in the Redstone R&D flight in November of 1956. Hydyne was a blend of 60 percent unsymmetrical dimethylhydrazine (UDMH) and 40 percent diethylenetriamine (DETA), making it more powerful—and more toxic—than the previously used ethyl alcohol fuel. Hydyne subsequently powered three Jupiter-C nose cone test flights and was used in launching America's first satellite, Explorer I, into orbit in January 1958. The launch of Explorer I rescued America's tarnished reputation in the wake of Russia's launch of Sputnik 1 and 2.

Morgan married a coworker and had children, continuing to work for North American Aviation and becoming a champion bridge player. She died in 2004. Her contributions to the Jupiter missions went largely unknown, as she had shunned publicity during her life and because she was a woman. Her colleagues referred to her as "America's first female rocket scientist," an achievement that few knew about until her son published a book about her life.

Nanotechnology

Nanotechnology is engineering, science, and technology all combined at the nano scale to study and manipulate molecules and atoms. The prefix "nano" means "one-billionth"; therefore, one nanometer is one-billionth of a meter. Nanotechnology, although a new science today, has actually been used since the Middle Ages. Painters in the premodern era were simply not aware that they were using nanotechnology to design stained glass windows. They would trap nanoparticles of gold in a glass matrix, creating a bright red color in the glass. Scientists now know that, depending on which metal is used and the size of its nanoparticles, a variety of colors can be generated in such glass.

Physicist Richard P. Feynman first formally introduced nanotechnology into the modern era by in his classic talk on December 29, 1959, at the annual meeting of the American Physical Society at the California Institute of Technology. He said that physics could progress more than it had in his day by gathering enormous amounts of information and storing it in unimaginably small spaces, such as the way information is stored in DNA molecules, holding all of a person's genetic information. Nanotechnology is work done at the molecular level, building larger structures atom by atom to create a new organization of molecules. Nanotechnology can be used across all the sciences to help improve the world, from objects invisible to the naked eye to the grand creations that allow us to move from point A to point B or planet to planet.

In the world of medicine, scientists are developing nanoparticles that can help deliver drugs to treat disease or infection in the human body, including cancer. Nanotechnology can also help us create instruments for space exploration, reduce the weight of aircraft, and improve spacesuit performance. Bio-nano robots applied as an outer layer of a spacesuit could detect damage and alert the user.

Nanotechnology is even involved in the food industry. Nanosensors are detectors that can test for harmful bacteria more affordably than sending produce out to be tested in labs. This may reduce the likelihood of catching salmonella or other bacterial disease from food.

Everything on the planet is made up of atoms, from the cars we drive to the air we breathe. They are invisible to the naked eye and even some microscopes. The size of nanoparticles is around 1 to 100 nanometers, whereas a red blood cell is 5.5 nanometers. To see nanoparticles and nanomaterials, we use specific types of microscope such as the scanning tunneling microscope. We also must manipulate nanoparticles or nanomaterials precisely. Nano materials can be constructed into shapes like tubes, wires, shells, or cones.

Nanotechnology continue to shape the way humans live, from medical advancements to handle cancer to the possible conquest of Mars.

Napalm

Napalm is a jellied fuel, often gasoline, used as an antihuman military weapon. It was first successfully tested in 1942 at Harvard University. Designed to stick to human skin, napalm also deoxygenates the air when it burns, creating a toxic, carbon-dioxide-rich environment. The United States first used napalm in Japan during World War II and then in the Korean and Vietnam Wars.

Napalm is named for its two thickening and gelling agents, naphthenic acid and palmitic acid. Chemists at Harvard University and Dow Chemical developed napalm in 1942 while attempting to develop a synthetic rubber in the face of wartime rubber shortages. When first introduced for military use, napalm

was used in flamethrowers and in bombs. Napalm and Napalm B, a variation on the original formula, is a highly flammable substance that burns skin and is impossible to wipe off. Dow Chemical made napalm in the 1960s until public protest, including by chemists, forced it to cease manufacture. A Pulitzer Prize-winning photograph of Vietnamese girl Phan Thi Kim Phuc running naked down a road after being burned by napalm led to increased public outcry against napalm. In 1980, the United Nations banned the use of napalm on humans. The United States signed the ban in 2009, on President Barack Obama's second day in office.

National Aeronautics and Space Administration (NASA)

Established by President Dwight D. Eisenhower (1890–1969) in 1958, the National Aeronautics and Space Administration (NASA) is today a group of 18 centers and facilities located throughout the nation. It has enabled scientists to reshape our understanding of the universe, engineers to improve aeronautics, the commercial sector to research and develop new products, and the public to share in the thrills of exploration and the spin-offs of cutting-edge technology. The organization has four principle organizations, or "mission directorates," that focus on aeronautics, science, space technology, and human exploration and operations.

NASA's creation was partly a product of the Cold War. In October 1957, the Soviet Union shocked the world by launching Sputnik, the first man-made satellite. Though the National Advisory Committee for Aeronautics (NACA) was considered one of the top institutions in the world for aeronautical research, the

most urgent research needs for the future appeared in space. Less than one year after Sputnik, NASA became the agency to address these needs, replacing NACA. NASA's new mission was to perform basic research and development for military and civil space exploration programs.

In the 1960s, NASA became known in the eyes of the public as the home of the astronauts and their quest for the moon. This mission, known as Apollo, had its genesis in President John F. Kennedy's (1917–1963) famous "Urgent National Needs" speech in May 1961. With a goal of landing a man on the moon before the decade was out, he wanted the entire nation to commit itself to achieving this goal quickly and efficiently—and before its rival superpower, the Soviet Union, could do that. As the Mercury and Gemini projects laid the technical and intellectual groundwork for the mission, the Apollo astronauts succeeded in carrying out Kennedy's challenge. On July 20, 1969, Neil Armstrong (1930–2012) and Buzz Aldrin (1930–) became the first humans to walk on the moon. Ten others followed them in subsequent Apollo voyages.

While the astronauts garnered all the headlines, NASA developed the first weather and communications satellites, giving birth to the satellite communications industry. In 1958, Explorer 1 became America's first man-made satellite, and Explorer 9 took the first picture of Earth from space in 1959. In 1960, the Television Infrared Observation Satellite, TIROS-1, became the first weather satellite in the world. That same year, Echo 1 became the first communications satellite launched by NASA. Two years later, Friendship 7, as part of Project Mercury, became the first "manned satellite," piloted by John Glenn (1921–2016).

This put NASA into the business of launching satellites with vehicles like Atlas, Titan, and Centaur. Cost benefits to NASA were significant. Because national policy precluded satellite companies from contracting directly with the launch vehicle manufacturers for launch services, the government, which owned the vehicles, could charge the makers of commercial satellites for the use of their vehicles, launch facilities, and services. NASA reached its 100th launch in the late 1990s.

The energy crisis of the 1970s marked a turning point for the United States in a number of ways. It

The 1958 Jupiter C Explorer satellite launch was one of NASA's early triumphs. A decade later, Project Apollo, a human spaceflight program that culminated in the moon landing, overshadowed the unmanned missions. (NASA)

changed the focus of NASA's aeronautical research fundamentally. Starting with NACA and continuing with NASA, the aeronautical emphasis had been on researching and building aircraft that would fly higher, go faster, and travel farther. Today, a commercial airline requires less than half the fuel to fly the same distance as an airplane in the 1970s. Key programs established by NASA, such as the Aircraft Energy Efficiency project (ACEE), helped achieve this.

NASA has continued the NACA tradition of groundbreaking aeronautical research in other areas as well, including aerodynamics and wind shear, using advanced research tools like wind tunnels and computer simulation. The X-15 program was a rocket-powered airplane capable of leaving the atmosphere and gliding back to earth. The F-8 digital fly-by-wire program enabled the development of high-performance aircraft. Other critical

advances included supercritical wings that enabled transonic aircraft to lessen the effects of shock waves.

Another significant new direction for NASA after the Apollo missions was “space science.” Planetary probes and landers have resulted in developing the core base of knowledge about our planet neighbors. The earliest type of spacecraft designed to make these planetary voyages were the Mariner (1962–1975) class probes, which visited both Venus and Mars. Conceived in 1960, these craft carried out flyby missions of the closest planets to the earth. They paved the way for more complex orbiting missions, eventually leading to an actual planetary landing. Mariner 10, the final in this series of probes, launched in 1973. It successfully reached Venus in February 1974, taking 4,000 photos of the planet. One month later, it made its first of three flybys of Mercury.

Pioneer 10 became the first spacecraft to travel through the asteroid belt, the first to make direct observations of Jupiter, and also the first to venture outside our solar system. At a distance of 7 billion miles from Earth, it holds the distinction as the remotest object constructed by humans. Now heading toward the Taurus constellation, it will take 2 million years to pass by one of the stars there. Pioneer 11 now drifts as a ghost ship headed for the Aquila constellation, which it will reach in 4 million years. Because of the potential contact with other beings on its long journey, American astronomers Carl Sagan (1934–1996) and Frank Drake (1930–) designed a plaque indicating who sent it. It displays a nude man and woman stand in front of a drawing of the spacecraft, along with a schematic of the earth’s position in the solar system.

NASA’s next planetary achievement was to land probes on the surface of another planet, and the first to do so were the Viking missions to Mars. Viking I and its sister ship Viking II, both launched in 1975, each consisted of an orbiter and a lander. The orbiters returned 52,603 images of the planet covering the entire Martian surface during all of its seasons. These photos also included images of both of the Mars moons. Other orbiter investigations included: water vapor mapping; thermal mapping; and data on ionospheric properties, atmospheric composition, and atmospheric structure. Lander investigations included: biological data; molecular analysis; inorganic analysis;

meteorology; seismology; magnetic properties; physical properties; and radio science that included celestial mechanics, atmospheric properties, and a test of general relativity.

Launching in 1977, *Voyager 1* and its counterpart, *Voyager 2*, gathered the most detailed and scientifically relevant knowledge ever assembled about Jupiter, Saturn, Uranus, Neptune, and the outer solar system. As luck would have it, these probes were in a perfect position to take advantage of a natural phenomenon that occurs once every 176 years. In the late 1970s, the largest planets in the solar system literally lined up to one side of the sun. Scientists knew that a carefully timed spacecraft sent from Earth could take advantage of this configuration and make an unprecedented tour of the planets in a single voyage. They provided the first detailed visual and scientific studies of the Jovian and Saturnian systems as well as the first close encounters with the outer solar system planets.

By the 1980s, NASA had turned much of its attention away from the expendable launch vehicle program and toward the space shuttle and low-earth orbit. Many engineers lamented this decision, as NASA was essentially forsaking two decades of reliable expendable rockets for a new system that had not launched even once and promised only minor advantages, along with the risky disadvantages of deploying satellites from a human-piloted ship. The *Challenger* disaster served as the catalyst for the commercialization of the expendable launch vehicle industry.

Orbiting space telescopes were the most dramatic scientific contribution by NASA to space science in the 1990s. But it also continued its planetary probes with Mars Pathfinder, which landed on Mars in 1997. To better explore the planet, it used a rover named Sojourner to investigate beyond the landing site with spectrometry to analyze rocks and soil. In 2012, two additional rovers, Opportunity and Curiosity, began to further explore the planet, discovering clear examples of a Mars that once had rivers and lakes, as well as an environment that could have supported microbial life. Mars Odyssey, Mars Express, and the Mars Reconnaissance Orbiter currently send back data from their orbital vantage points.

NASA is also significantly involved in better understanding life on earth. In 1999, it launched Terra

as the first of the Earth Observing System craft. Terra's mission is to better understand the changing climate on earth through five sensors that investigate interactions between the ocean, land, the atmosphere, and radiant energy. Aqua is another earth science satellite, and, as its name indicates, its focus is on the earth's water cycle.

At the start of the 21st century, NASA made a giant leap into space with the International Space Station (ISS). This effort capitalized on the success of Skylab, the United States' first orbiting station. Launched in 1973 atop a Saturn V rocket, Skylab proved that humans could live and work in a zero-gravity environment for several months at a time. Skylab also photographed the earth and returned astronomical observations with its Apollo telescope mount. Its mission ended in 1979 when Skylab reentered and burned up in the earth's atmosphere over Australia.

Unlike Skylab, the International Space Station (ISS) has truly been an international endeavor, with contributions from NASA, the Russian Federal Space Agency, the European Space Agency, the Japan Aerospace Exploration Agency, and the Canadian Space Agency. Each of these agencies built various modules for the ISS, and when each was completed, a space shuttle or Soyuz capsule delivered it to orbit. The International Space Station received its first human residents on November 2, 2000. Since that time, over 200 people, in crews of 6 at a time, have taken shifts on the station. On its 10th year in flight, it had logged over 1.5 billion miles and orbited the earth over 57,000 times. The NASA Authorization Act of 2010 established the American goals for the ISS, which include "human health and exploration, technology testing for enabling future exploration, research in basic life and physical sciences, and earth and space science."

Today, NASA divides its interests into four main mission directorates. The Aeronautics Research Mission Directorate (ARMD) works on improving the U.S. air transportation system (safety, environmental impacts, and air traffic congestion) and also furthering green aviation (increased fuel efficiency, better flight planning, lower emissions, and reduced noise). The Human Exploration and Operations (HEO) Mission Directorate concentrates on tasks in and beyond

low-earth orbit, including the International Space Station, space life sciences, and advanced exploration systems. The Space Technology Mission Directorate (STMD) develops new technologies that NASA needs to achieve its space missions through partnerships with industry and academia. Finally, the Science Mission Directorate investigates the relationship between the earth and the sun, the solar system, and the universe.

These missions are carried out at the following 10 NASA centers and 8 facilities:

- Ames Research Center: Mountain View, CA
- Armstrong Flight Research Center: Edwards, CA
- Glenn Research Center: Cleveland, OH
- Goddard Space Flight Center: Greenbelt, MD
- Goddard Institute for Space Studies: New York, NY
- Independent Verification and Validation Facility: Fairmont, WV
- Jet Propulsion Laboratory: Pasadena, CA
- Kennedy Space Center: Cocoa Beach, FL
- Langley Research Center: Hampton, VA
- Marshall Space Flight Center: Huntsville, AL
- Michoud Assembly Facility: New Orleans, LA
- NASA Shared Services Center: Kiln, MS
- Plum Brook Station: Sandusky, OH
- Stennis Space Center: Hancock County, MS
- Wallops Flight Facility: Wallops Island, VA
- White Sands Test Facility: Las Cruces, NM

The future promises a bold program of new exploration, cutting-edge technology, and scientific research. The Orion spacecraft and the Space Launch System rocket plans to send astronauts to an asteroid in the 2020s and to Mars in the 2030s. NASA continues to work with commercial companies to develop spacecraft to transport astronauts and cargo to low-earth orbit. In aeronautics, it is part of a government team to create the Next Generation Air Transportation System (NextGen) that will fly in 2025.

Primary Document: Letter of President Dwight Eisenhower to Keith Glennan, Retiring Administrator for NASA (1960)

On December 29, 1960, President Dwight Eisenhower wrote a letter to Keith Glennan, the retiring administrator for NASA who had held the title since its founding in 1958. In the letter, the president praises Glennan for the many accomplishments he shepherded into existence in his tenure, including launching satellites and deep space probes.

December 29, 1960

Dear Keith:

Under your leadership, the National Aeronautics and Space Administration, since its inception on October 1, 1951 has compiled a record of achievement of which every American can be justly proud. Therefore, while accepting your resignation as Administrator of NASA, effective January 20, 1961, I wish to express my thanks for the great contribution you have made.

Our Nation's non-military aeronautical and space activities are vastly expanding human knowledge phenomena in the atmosphere and outer space and applying this knowledge for the benefit of all mankind. The progress that is being made is striking testimony to your ability to quickly bring together an effective and dedicated staff, to plan an imaginative program of space exploration, and to implement this plan with vigor and determination.

In little more than two years, NASA has successfully launched meteorological satellites, such as Tiros

and Tiros II, that promise to revolutionize methods of weather forecasting; demonstrated the feasibility of satellites for global communications by the space-shot launching of Echo I; produced an enormous amount of valuable scientific data such as the discovery of the Van Allen Radiation Belts; successfully launched deep-space probes that have established the greatest range over which man has tracked, and made gratifying progress toward the goal of manned space flights.

Because of the organization and program you have helped to create, Americans can look forward to a remarkable time in space exploration. It is hard to realize—yet inexorably true—that the near future will hold such wonders as the orbital flight of an astronaut, the landing of instruments on the moon, the launching of the giant Saturn, and the reconnaissance of Mars and Venus by unmanned vehicles.

As you return to private life, you carry with you my appreciation, respect, and friendship. I wish you a long, happy, and healthy future.

DWIGHT D. EISENHOWER

The Honorable T. Keith Gisanan
Administrator

National Aeronautics and Space Administration
Washington, D. C.

National Science Foundation (NSF)

As a counterpart to the National Institutes of Health (NIH), whose headquarters currently reside in Arlington, Virginia, the National Science Foundation's (NSF) mission statement notes that its purpose is "to promote

the progress of science; to advance the national health, prosperity, and welfare; and to secure the national defense." As an independent federal agency established by the U.S. Congress in 1950, the NSF's goals are to strategically cultivate knowledge among *nonmedical* areas of science and engineering—this is where it

differs from the NIH. It focuses on the study of these two fields and also supports education within them.

Before World War II, the study of science and engineering was not a concern for the government. It left that in the hands of private and philanthropic foundations. Military research was unorganized and not well communicated; redundant studies might be done because nobody knew if others had researched the same topics. The National Science Foundation was created once the nation saw that the organized study of science, technology, and education was crucial to society.

The United States saw that science and engineering had aided in its World War II victory and created the NSF to promote the welfare of society. President Harry S. Truman signed it into existence on May 10, 1950 with the NSF Act. With it also arose a National Science Board, which included a director and 24 part-time members. The following year, President Truman nominated Alan T. Waterman as the first director of the NSF.

The NSF offers grants, but contrasting with its medical counterpart, it does not have a lab. It receives over 50,000 proposals annually in fields that include mathematics, computer science, and other sciences and has a budget of \$7.5 billion; it funds only 20 percent of proposals. A proposal review consists of three phases: proposal preparation and submission (Phase 1), proposal review and processing (Phase 2), and last, award processing (Phase 3). Phase 1 takes up to 90 days from the announcement of a funding opportunity. Phase 2 takes up to six months, and consists of reviews by the NSF leadership. Phase 3 lasts up to a month; the Division of Grants and Agreements coordinates more reviews, making sure that the request has been rightfully rewarded, finalized, and notified.

Since the early 1950s, the NSF has strengthened undergraduate teaching, funding many programs and schools. In June 1953, the NSF supported its first colleges by sponsoring four science institutes to encourage summer research, and it has since provided funds for programs for physics, biology, and mathematics. Tufts University became one of the earliest colleges to accept funding from the National Science Foundation for this purpose. The NSF believes that it is crucial for students to study subjects such as computer science, mathematics, chemistry, and more.

Director and astronomer Dr. France A. Cordova, a former president of Purdue University, joined the NSF in March 2014. Currently, about 2,100 people work at the foundation.

Noyce, Robert (1927–1990)

Robert Noyce, an entrepreneur, physicist, and inventor, played a key role in the development of the integrated circuit, which is one of the most fundamental technologies that today's computers are built around. He is also a cofounder of Fairchild Semiconductor and Intel Corporation, landing him the nickname "mayor of Silicon Valley."

Noyce was born in Burlington, Iowa, on December 12, 1927, the youngest of four brothers, to Ralph Brewster and Harriet May Norton. The Noyce family moved to Atlantic, Iowa, after Noyce's birth and then to Decorah, Iowa, when he was eight years old. After two years, they moved to Webster City, Iowa, and to Grinnell, Iowa, two years after that. Noyce spent the remainder of his childhood in Grinnell. Bored with high school physics, he took a college-level physics course, inspired to do so by a Grinnell College physics professor whose lawn he mowed. Noyce's parents

moved to Sandwich, Illinois, after he graduated high school; Noyce remained at Grinnell College.

Noyce excelled at college academics and extra-curriculars such as the swim team and theater. He graduated with honors, with a BA in physics and mathematics in 1949. Noyce was exposed to one of the first ever transistors in one of his physics classes, which is what sparked his passionate interest in the subject. He would go on to base his 1953 MIT PhD dissertation on transistors.

Noyce was not the only one in his family with an interest in technology and physics. One of his brothers taught chemistry, and another worked for IBM in San Jose, California. His third brother, perhaps influenced by their father, joined Yale's Divinity School to study theology.

After completing his education, Noyce scheduled interviews at IBM, RCA, GE, Bell Labs, and more. Philco was trying to get into the transistor business and hired Noyce in 1953. He felt that the company lacked scientific talent aside from himself and some other PhDs who had been hired shortly after him. In 1956, Bill Shockley, known as the inventor of the junction transistor, recruited Noyce to work in his semiconductor laboratory. Noyce moved to California to work under Shockley, but he was frustrated with Shockley's management skills. Noyce and seven of his peers splintered off and started what would become Fairchild Semiconductors Corporation in Santa Clara, California.

There, he presented his concept of the integrated circuit, and Fairchild believed it would revolutionize electronics, taking it on as a core mission. Noyce and his colleagues created the first ever integrated circuit (IC), a complete circuit contained on a wafer of silicon—more commonly known as a “chip.” Noyce and Jack Kilby received the patent for this piece of technology.

Noyce stayed with Fairchild as its director of research and development until 1968, when he and two coworkers, Andrew Grove and Gordon Moore, founded Intel Corporation to make microprocessor chips. These components can be thought of as the brains of modern computers. Along with processing arithmetic, microprocessors control all the functions of a computer system. Noyce worked in various upper-executive positions at Intel up until 1978, when he transitioned to the position of chairman at the Semiconductor Industry Association.

Noyce's several inventions and innovations over the course of his life earned him many awards from the scientific community, including the IEEE Medal of Honor in 1978 and the Charles Stark Draper Prize from the National Academy of Engineering. He was also awarded the National Medal of Technology by President Ronald Reagan in 1987. If not for the innovations that Noyce and his colleagues created, technology might be decades behind where it is today in the Digital Age.

Noyce married twice. He had four children with his first wife, Elizabeth Bottomley, who had studied English at Tufts University in Medford, Massachusetts. They met when she directed a drama project and married in 1953. Late in 1974, Noyce left Elizabeth to marry an Intel executive, Ann Bowers. The two would stay together until Noyce succumbed to death in 1990 of a heart attack.

Primary Document: Personal Interview with Robert Noyce for the IEEE History Center (1975)

This is a transcript of a personal interview with Robert Noyce for the IEEE History Center in Hoboken, New Jersey, conducted in 1975 by Michael Wolff. The interview goes into great detail about Robert

Noyce's involvement with the creation of electrical components that are critical in our world today—mainly the integrated circuit and advancements in transistor technology. This document is important

because it gives a firsthand account of the integrated circuit's invention and experimentation, as well as what motivated Mr. Noyce and his colleagues to create this important piece of technology. The interview also goes into Robert Noyce's personal background and what got him interested in physics.

Wolff:

Let's go back to the actual invention. When did it get invented? I don't mean the date, but what was the critical step? It was after you had the planar technology.

Noyce:

Yes.

Wolff:

Can you retrace who thought what or said what to whom or did what and where you fit in this?

Noyce:

We were having a review of the patent application on the planar transistor, as I recall. John [Lippincott J.] Ralls was there. He was Fairchild's patent attorney at the time. We were thinking that we ought to try to cover as broad an area as possible out of this development. We sort of assigned our selves to the task of doing what we could, in conceptualizing, to cover as broad an area as we could with that. That was in the back of our minds anyway, but I suppose that the actual invention came down to the point where one day one comes in to the lab and says, "Hey, here's a good way to do this. Why don't we do it this way?" I'd have to look up the actual data, but it was probably back in '59.

Wolff:

Without trying to recall the date can you recall the circumstances and tell me about that day?

Noyce:

I did not see it as a very unusual day. I just went in and probably had a discussion with Gordon Moore or Vic Grenich or somebody like that initially. I said something like, "Hey, here's a way to do the whole job of making some logic circuits instead of making individual transistors." There wasn't any need for describing what the utility of the thing would be around that shop. That was well known. It was a question of coming up with a compatible set of schemes to come up with the structures that would work electrically. Then we proceeded to try to realize the structures and file patent applications on it.

Wolff:

Let's try to tie down the organization here. What was your position at that time and who was "we"?

Noyce:

Fairchild was still a pretty tightly knit little group at that time. There were the eight founders that had been in there. Obviously the staff had expanded, but most of the technical work was being done by that group of eight founders, which included Sheldon Roberts who was a metallurgist, Jean Hoerni who was a physicist, Gordon Moore who was a chemical physicist, Vic Grenich who was in electronics, Jay Last who was a physicist and myself. And there were a couple of engineers.

Wolff:

You were a physicist.

Noyce:

I was a physicist by training, and had my training in solid-state physics. More accurately it was physical electronics. Solid-state physics was not yet a respectable field at MIT. We were a tightly knit little group. We had worked together at Shockley and knew each other pretty well. There was an awful lot of batting of ideas back and forth and criticism of other people's ideas, "Hey, that won't work because of this." Then we'd go back and say, "Well, let's devise a scheme that will work." It was a question of having rather vague concepts of insulators, isolation, interconnection and the photoengraving for the pattern. We drew on our bag of tricks these particular elements. Those elements in combination made the integrated circuit. Perhaps there was the "I've got it" type of thing, there is a way that will work. Once you have a way that will work conceptually then you start refining it to make it work better. Up until this point it was sort of, "Gee, wouldn't it be nice if you could?"

Wolff:

Was there such a moment like that on this day that you recall as being ordinary?

Noyce:

Yes. I remember sketching it out on the blackboard for John Ralls, who was the patent attorney. Did I do it some other time for the other people? Very likely not on the blackboard, but I probably said, "Hey, why don't we do this."

Wolff:

What did you sketch for Ralls?

Noyce:

The sketch I did for Ralls was very similar to what is in the patent application.

Wolff:

Do you mean the patent for the planar transistor?

Noyce:

No. I mean the one for the integrated circuit patent. It shows the various elements and how they are constructed conceptually. It shows the transistor, the diode and the resistor as being three elements that we could make easily at that time.

Wolff:

I just lost the thread here because you had been talking about a meeting with Ralls to discuss the planar transistor.

Noyce:

Yes. No, this was a later one then. It was after he was throwing out the challenge as to what could be done with it beyond that—as any good patent counsel does.

Wolff:

You remember him throwing out the challenge.

Noyce:

Yes.

Wolff:

Then you began thinking about circuits.

Noyce:

Yes. Thereafter there was the insight that with the addition of that insulating layer the circuits could be done. There were a couple of other incidental inventions that came along at that time which were more critical to the immediate task that we had at Fairchild. We were trying to make high-frequency transistors. One of the problems with high-frequency transistors was that the structures were extremely small and contacts had to be made to extremely small areas. One of the first concepts in there that was patented was, “Okay, let’s make a big contact but have the metal film over this silicon dioxide—which is the insulator—and have a hole in the silicon dioxide that is very small to make a contact through this very small area.” That patent was filed, and after that immediately came the idea, “A metal strip can be put over the PN junction without shorting it out.” As soon as that can be done the entire circuit can be interconnected. It was a progressive buildup of the bits and pieces of the technology that made the entire thing possible.

Nuclear and Radiation Accidents

The International Atomic Energy Agency (IAEA) defines a nuclear or radiation accident as any incident that creates significant consequences to a facility, the environment, or people. To date, the worst nuclear accident happened at the Chernobyl plant in Ukraine in 1986. According to the IAEA, the United States has experienced 12 nuclear accidents that have resulted in multiple fatalities or over \$100 million in damage. Radiation accidents and incidents are too numerous to count.

A number of political measures sped nuclear power’s development in the post–World War II period. Although nuclear power held many promises, it also contained inherent dangers. Nuclear fission in a reactor releases heat, which is carried away by coolant (usually water, gas, or liquid metal) to heat water and

create steam to turn turbines and produce electricity. Control rods pushed into a reactor regulate the amount of heat produced in a reactor by absorbing the neutrons that cause fission. But if the heat within a reactor exceeds that being carried away by coolant, components of the reactor can begin to melt, releasing heat and radioactivity and possibly causing explosions if the energy released is too great.

The EBR-I reactor in eastern Idaho became the first functional nuclear power plant in December 1951 when it produced enough electricity to power four lightbulbs. Yet, during extended experimentation with this early design, scientists there became puzzled by unexpected responses to changes in coolant flow within the reactor. In November 1955, during coolant flow tests, the reactor partially melted down. Researchers discovered that the unanticipated changes had been caused by unforeseen expansion of the uranium fuel

rods within the reactor, and the reactor was repaired for further operation.

Another partial meltdown occurred in July 1959 at the Sodium Reactor Experiment in Simi Valley, California, which used liquid sodium as a reactor coolant. (Water used as reactor coolant must be subjected to high pressure, but liquid sodium does not require this stipulation.) The oil-like fluid tetralin was used in a support system to cool and stabilize the pump removing heated sodium from the reactor. But when tetralin seeped into the coolant system itself, the molten sodium decomposed the oily substance, leading to the clogging of several channels designed to remove heat from the reactor. The resulting overheating damaged many of the reactor's fuel components. Operations continued for several days until reactor staff noticed unusual behavior, at which point the reactor was shut down. Inspectors found that several pieces of the fuel elements had dislodged and either gotten stuck in the reactor's transport systems or fallen to the floor of the reactor. Over the following months, Atomics International, the private company managing the reactor, cleaned and repaired the reactor and installed a new core, with operations resuming in September 1960.

Later accidents were more serious in scope. On January 3, 1961, the SL-1 reactor located at a U.S. Army facility in eastern Idaho was being prepared for reactivation after an extended shutdown over the Christmas and New Year's holidays. The main control rod in the reactor needed to be withdrawn a few inches from the reactor to be reattached to its drive mechanism. The rod was suddenly withdrawn several inches too far, causing the inside of the reactor to immediately heat to extreme temperatures and vaporize the water inside the reactor. The pressure generated caused the other control rods to shoot out of the reactor and even made the entire reactor jump over nine feet in the air. The operator who had removed the main rod was killed almost instantly, another employee was impaled by a control rod, and one more was found unconscious nearby. Though a number of theories circulated about why the rod was suddenly withdrawn, investigators determined that the most likely explanation was that it had broken loose and been removed by accident. The site's remote location in the Idaho desert, combined with the SL-1's building's containment capabilities,

limited the threat of broader radioactive exposure, though the incident remains the only known U.S. nuclear meltdown that resulted in immediate fatality. As a consequence of the incident, the army shut down the reactor and buried the remains, and future nuclear designs for both public and private plants were designed to ensure that the removal of a single control rod could not generate the amount of excess heat that had caused the accident.

As nuclear incidents grew more severe in scope and attracted media attention, many Americans began to reconsider the viability of nuclear power. In the late 1960s and early 1970s, a burgeoning environmental movement that demanded new rules for clean air and clean water folded nuclear power into its list of environmental concerns. Observers such as plant physiologist Barry Commoner and consumer advocate Ralph Nader, along with others, pointed out that no energy source presented the risk of sudden and catastrophic disaster that nuclear power did. The 1966 partial meltdown of Fermi-1 in Detroit inspired local newspaper writer John G. Fuller's *We Almost Lost Detroit* (1975), a visceral account of the accident and the extended, troubled repair process. The 1975 fire at the Browns Ferry plant in Alabama resulted in enhanced fire protection standards for nuclear plants but did little to quell rising antinuclear protest.

Proponents and detractors of nuclear power also argued vociferously about the disposal of used radioactive nuclear material. Antinuclear advocates were skeptical that used material could be contained, predicting that it would escape underground containment vessels and make its way back to the surface and into the water supply. Few Americans wanted spent nuclear rods buried anywhere near their towns or cities.

Disillusioned observers inside the industry itself also took their concerns to the news media. Karen Silkwood, an Oklahoma nuclear power worker, died in a car accident while delivering evidence of misconduct at her workplace to a *New York Times* reporter, which brought accusations of corporate foul play from antinuclear activists. In 1976, three senior nuclear engineers turned against their employers, accusing the industry of lax adherence to safety standards and charging the Nuclear Regulatory Commission (which had replaced the Atomic Energy Commission in a

1974 government reorganization) of working hand in hand with private companies to conceal evidence of safety violations. The television newsmagazine *60 Minutes* ran a story about one of these industry whistleblowers, bringing the allegations to the attention of the general public.

The most serious nuclear accident in the United States, the March 1979 Three Mile Island disaster in Pennsylvania, most directly led to the decline of the U.S. nuclear power industry. The incident combined all of the potential fears about nuclear danger: technical malfunction in the form of a stuck valve, poorly trained operators who could not tell that the reactor's relief mechanism was not working properly, and incompetent management that did not know that a meltdown was occurring until it was well underway. President Jimmy Carter, who toured the plant with Pennsylvania's governor that April, established a special committee to investigate the accident. The resulting report laid heavy blame upon both the plant's private operators and NRC regulators.

Though the meltdown caused no immediate fatalities, nearly 140,000 Pennsylvanians evacuated their homes due to concerns about radioactive exposure, and the cleanup lasted over 14 years, with costs reaching \$1 billion. Stalwart nuclear proponents like physicist Edward Teller and Oak Ridge National Laboratory head Alvin Weinberg attempted to assuage Americans' fears by pointing out that no one had died in the accident and that the release of toxic radiation had been minimal. Nuclear advocates conceded that the American regulatory structure needed reform, pointing to France and Japan as examples of nations where the nuclear power system had been safely and competently established. But the multiple levels of failure on display at Three Mile Island were too much for the public to stand, as protests persisted in the United States and around the world. Public opinion in the United States turned sharply against nuclear power as a result of the accident (with the 1986 Chernobyl catastrophe in Ukraine raising nuclear fears to even higher levels), and no new nuclear power plants were approved for construction in the United States until 2012.

A number of smaller accidents at nuclear plants occurred steadily after 1979. In January 1982, for

example, a steam tube rupture at the Ginna Nuclear Generating Station in Ontario, New York, released radioactive material into the environment. At the Nine Mile Point station in Scriba, New York, malfunctions forced a plant shutdown in December 1987, and safety concerns spurred the shutdown of the FitzPatrick reactor in the same city in November 1991. In March 1993, equipment failures shut down Sequoyah Unit 1 in Soddy Daisy, Tennessee. Unmonitored wear and tear on reactors as the years passed generated a further source of concern.

After the 2011 Fukushima Daiichi disaster in Japan galvanized renewed worldwide fears, an annual survey of American utility executives identified nuclear safety as the number-one concern within the power industry, and license extensions for existing American reactors were expected to come under enhanced scrutiny.

In 2012, the Union of Concerned Scientists, a nonprofit advocacy organization, claimed that the leakage of radioactive materials was a significant problem for 90 percent of American power plants. The Natural Resources Defense Council, the National Wildlife Federation, the Sierra Club, and other environmental groups continued their antinuclear protests, which had hardly lulled since Three Mile Island. Though there were no major nuclear meltdowns in the United States after 1979, the combination of sporadic equipment failures and human error meant that a variety of problems persisted in the industry.

Ochoa, Ellen (1958–)

Dr. Ellen Ochoa is an American scientist, inventor, and astronaut, and the current director of the Lyndon B. Johnson Space Center (JSC) in Houston, Texas. She was the first female Hispanic astronaut to go into space and the first Hispanic person to head the JSC.

Ochoa was born in Los Angeles, California, but was raised in La Mesa, California, a suburb of San Diego. Her parents were divorced when she was a teen. Ochoa's mother attended college while raising her four children, providing inspiration for Ochoa's academic success.

Ochoa graduated from Grossmont High School in 1975 as the class valedictorian. A classically trained flutist, she considered pursuing a music degree in college, but she decided to study science because many of her friends from her high school calculus class were planning to major in science and engineering. While pursuing advanced studies in science, Ochoa maintained her involvement with music, receiving the student soloist award from the Stanford Symphony Orchestra as a graduate student. She earned her undergraduate degree in physics at San Diego State University (1980). She went to graduate school at Stanford and earned her master's degree in 1981 and her doctorate in electrical engineering in 1985. She then accepted a position as research engineer at the Energy Department's Sandia National Laboratories in Livermore, California, working in the Imaging Technology Branch on optical inspection systems.

In 1987, Ochoa was accepted for the NASA training program, one of 100 finalists out of 2,000 applicants. The next year, she began work for NASA as the chief of the Intelligent Systems Technology Branch at the Ames Research Center in California, working on computational systems for space missions. Ochoa began her yearlong training process as an astronaut in 1990. Ochoa has flown in space four times, for a total of over 978 hours in orbit. Her first space flight was in 1993, when she was stationed aboard the space shuttle *Discovery* for a nine-day mission. The objective of the mission was to learn how solar activity affects the earth's climate and environment by conducting a variety of atmospheric and solar studies. One of Ochoa's tasks was to deploy and capture the Spartan satellite, which studied the sun's

corona and solar winds, using the 50-foot Remote Manipulator System (RMS) robotic arm.

The sun proved the focus of Ochoa's second space flight in 1994. She served as the payload commander on the STS-66 Atlantis Atmospheric Laboratory for Applications and Science-3 mission. During this flight, the crew continued investigations into the sun's energy during an 11-year solar cycle to determine how these fluctuations might affect the earth's climate and environment. Ochoa used the RMS again during this mission, this time to retrieve the CRISTA-SPAS atmospheric research satellite.

Ochoa's third space shuttle mission on the *Discovery* in 1999 was significant for the being the first time that the shuttle docked to the International Space Station. She visited the International Space Station for a second time during her final space shuttle mission on the *Atlantis* in 2002. During this mission, she and crewmembers Dan Bursch and Carl Walz used the station's robotic arm to install the S-Zero Truss and to maneuver spacewalkers around the station.

In 2002, Ochoa became the deputy director of flight crew operations at the Johnson Space Center, NASA's human space exploration division, and in 2006, she took on responsibility as the director of flight crew operations. Since 2012, she has served as director of the Johnson Space Center.

Ochoa also serves on the board of Service Corporation International, is an ex-officio board member of the Houston Technology Center and the Bay Area Houston Economic Partnership, and is director emerita of the Manned Space Flight Education Foundation Inc., which operates Space Center Houston. She is also chair of the Nomination Evaluation Committee for the National Medal of Technology and Innovation.

Ochoa has been awarded numerous honors including the Distinguished Service Medal, the Exceptional Service Medal, the Outstanding Leadership Medal, and four Space Flight Medals from NASA. Other awards include the Harvard Foundation Science Award, the Women in Aerospace Outstanding Achievement Award, the HENAAC (Hispanic Engineer National Achievement Awards) Engineer of the Year, the Hispanic Heritage Leadership Award, membership in the California Hall of Fame, and San Diego State University Alumna of the Year. In addition, she has

four schools named after her: two in California, one in Texas, and one in Washington State.

Orshansky, Mollie (1915–2006)

Mollie Orshansky, also known as "Ms. Poverty," was responsible for the research in food economics that developed the federal government's poverty thresholds. These thresholds track the estimated number of people

Economist and statistician Molly Orshansky developed the Orshansky Poverty Thresholds, which used nutrition statistics to calculate cost of living, to determine poverty rates. (Michael Williamson/The Washington Post/Getty Images)

in the United States living in poverty. She differentiated the thresholds not only by family size but also by farm/nonfarm status, the gender of a family's head, the number of family members who were children, and aged/nonaged status.

Mollie Orshansky was born in New York City to Ukrainian immigrant parents. She grew up in poverty and later said that her family often did not have enough food. She was the first in her family to graduate from high school and the first to attend college. She graduated from Hunter College in 1935 with an AB in mathematics and statistics. She also studied economics and statistics at the Department of Agriculture Graduate School and at American University.

After graduating from Hunter College, Mollie Orshansky worked for the Department of Health in New York City as a statistical clerk. In 1939, she moved to Washington to take on the same position for the U.S. Children's Bureau, which handled all matters pertaining to the welfare of children in the United States. She would work in a number government agencies over her career, including the National War Labor Board, U.S. Wage Stabilization Board, and U.S. Department of Agriculture (USDA).

Before her work as a food economist, she developed food plans in unison with the USDA that led to the creation of "poverty lines," which were amounts of income below which a family could be considered poor and in need of help. She accomplished this by collecting and analyzing food consumption data and tracking the expenditures of American households.

President Lyndon Johnson declared a "War on Poverty" in 1964 that utilized Orshansky's work. Johnson's administration hoped to reduce the national poverty rate, which stood at 19 percent. Orshansky was working at the Social Security Administration in the Office of Research and Statistics at the time, and her work was published in the Social Security Bulletin. The Office of Economic Opportunity used Orshansky's work as a guideline to determine the official federal definition of poverty. Her efforts won her the Commissioner's Citation from the Social Security Administration in 1965 and the Distinguished Service Award from the U.S. Department of Health, Education, and Welfare for her leadership.

Orshansky's thresholds provided the country with a means of identifying the groups in our society with the least resources. Her work laid a foundation for

methods of research in the field of statistical poverty analysis. The thresholds she developed are updated every year by the U.S. Census Bureau.

Packet Switching

Packet switching is the concept of breaking down information into smaller pieces to be sent independently through various channels and reassembled into original order at the destination. The concept was first introduced by a Department of Defense research program at the Rand Corporation and was originally called "distributed adaptive message block switching" by its inventor, Paul Baran, in the 1950s. Donald Davis coined the term "packet switching" when he independently introduced his research in the concept of small block data transmission networks at the National Physical Laboratory in the United Kingdom in the 1960s.

Both basic concepts focus on creating robust and reliable data communication networks to more efficiently transmit large volumes of data from different applications simultaneously, even after network nodes are attacked or taken offline. Over time, the concept of packet switching in networks led Leonard Kleinrock to help in the development of ARPANET, the network that would eventually evolve into what we know as the Internet.

Before the concept of packet switching in networks, communication networks had limited efficiency due to the necessity for network channels to stay connected for the duration of the entire transmission. Packet switching avoids this by breaking down the information into limited byte-size pieces composed of

two basic parts: the header and the payload. The header contains information about the source, destination, and metadata used by the network to direct the packet through the network to the specified destination. The payload is the actual information intended for use at the specified destination.

Since the introduction of packet switching, the concept has spurred the creation of a variety of different networks, all with unique operating procedures, computing languages, and network configurations, which proved difficult for network-to-network communication. This challenge was addressed using Kleinrock's queueing theory, via Internet Protocol suite (also known as TCP/IP, transmission control protocol, and Internet Protocol). Also known as metadata, the TCP/IP provides error corrections and organization for reliable data transmission. Using a variety of algorithms, metadata also provides detailed controls and instructions about the payload delivery, such as delivered data arrangement, key payload elements, file type, information source, who can access the payload, and other technical network navigation protocols.

Modern Internet connectivity emerged with the introduction of Internet service providers; the first commercial provider was The World, based in Massachusetts, in November 1989. In the relatively short time since the conception of this efficient communication network, it has been the most instrumental tool in transforming our world and the way we live today. The invention of the personal computer expanded our personal capabilities, but the concept of the packet-switching network facilitated our transformation into a worldwide, interconnected species capable of rapid information sharing to effect immediate attention or action as needed.

Particle Accelerator

Particle accelerators are machines that propel charged particles to very high speeds using electromagnetic fields. Researchers can collide two beams of accelerated particles in order to study the resulting matter and the forces involved. It is presumed that conditions in modern high-energy particle accelerators reproduce conditions similar to those at the birth of our universe—the Big Bang—giving us a window into how it was created in the first place.

Particle accelerators are a product of the 20th century. Until then, scientists could theorize and try to prove hypotheses with mathematics, but advancements couldn’t be made unless theories could actually be tested. Particle accelerators have opened the door to our modern-day understanding of the building blocks that turn energy into matter.

There are two types of particle accelerators: linear and circular. Both use electromagnetic waves to speed up atomic particles, and the more energetic a particle can be made, the better researchers can determine the structure of its matter. Linear accelerators push a beam of particles down a long vacuum toward a target at the end of a tube, where detectors record the results. Circular accelerators push particles around in a circle, gaining energy with each pass until they hit their intended target and an array of detectors records the results. The first circular particle accelerator was created in 1930 at the University of California, Berkeley by Ernest Lawrence and M. Stanley Livingston and accelerated hydrogen ions within a chamber less than five inches in diameter.

All particle accelerators are made of the same basic components. There is a particle source that provides the particles to be accelerated; a copper tube in which the particle beam travels through a vacuum; a klystron, a microwave generator that makes the waves that the particles ride on; electromagnets to steer and

confine particles to a tight beam; targets, the particle collision points; detectors, which measure pieces and radiation created by the collision; vacuum systems that remove all particles from the tube; cooling systems to remove heat produced by the magnets; a computer that controls accelerator operations and analyzes data; shielding to protect anyone nearby from the radiation produced; monitoring systems used to see inside and measure radiation to determine what happened in the accelerator; an electrical power system to provide electricity; and storage rings to temporarily store beams not being used.

When scientists first started using particle accelerators, they discovered hundreds of particles smaller than the three well-known subatomic particles: protons, neutrons, and electrons. They also recognized the correlation between the amount of energy put into the accelerator and the number of particles they could detect. As scientists began to classify and organize these particles, a standard model of the atom became clear. The model outlined the ability to group matter into the following categories: fermions, which make up matter and antimatter; leptons, elementary particles like electrons and neutrinos; quarks, basic particles that hold the nucleus together; antimatter, opposite particles to quarks and leptons; hadrons, composite particles like protons and neutrons; and bosons, particles that carry force and help to give energy mass.

The array of subatomic particles that result from particle accelerator collisions are also thought to control the four fundamental forces: the strong force, which holds the nucleus of the atom together; the weak force, which is involved in radioactive decay; electromagnetism, which controls interactions between charged particles; and gravity, which acts as an attractive force based on mass and distance. Experiments in particle accelerators have shown us that under the right conditions, the electromagnetic force and the weak force can combine to become the “electroweak” force, leading other scientists to believe that the different forces may have stemmed from one unified force that existed long ago.

Much of our understanding of particle physics is all thanks to the largest, most expensive, and most complex experiment ever constructed in human history: the Large Hadron Collider at CERN in Geneva,

Switzerland. This is a circular underground structure with a circumference of 27 kilometers (17 miles), and at a depth ranging from 50 to 175 meters (164 to 574 feet) underground. The total operating budget of the LHC runs about \$1 billion per year, and all costs considering, the total cost of finding the Higgs boson ran about \$13.25 billion. This machine alone can be credited for expanding our understanding of the workings of the universe to the limits that we currently hold.

In the United States, the Relativistic Heavy Ion Collider (RHIC) was installed in Brookhaven National Laboratory on Long Island, New York, in 1994. Particle accelerators have become part of popular culture as an icon of our modern world and a testament to our quest to understand the universe around us. But most people don't know just how many particle accelerators there are in the world.

With tens of thousands of particle accelerators in use across the planet, most people do not understand the major role these machines play in our everyday lives. Although they are best known for particle physics research, particle accelerators also help us to create cancer-destroying beams, kill bacteria to prevent food-borne illnesses, improve jet fuel, develop shrink wrap

and diapers, develop semiconductors, clean the air, diagnose medical conditions, and produce powerful x-rays for medical research. They help DNA researchers to analyze and define how the ribosome translates DNA into life. Particle accelerators have profoundly expanded our knowledge and have been crucial in improving human lives.

Primary Document: Press Release Issued by CERN, the European Organization for Nuclear Research (2012)

As of today, the leading ideas in particle physics are based around a scientific proposal called the Standard Model. One of the leading academics behind this understanding is Peter Higgs, who, with his colleagues, predicted the existence of a specific subatomic particle that causes other subatomic particles to come together and form atoms, essentially giving mass to the universe. On July 4, 2012, at the Large Hadron Collider in Geneva, Switzerland, scientists received data from the largest and most expensive experiment in human history. The data gave concrete proof that detected the existence of this particle, lending credence to the accuracy of the Standard Model. For Higgs's revolutionary ideas, he was awarded the Nobel Prize in Physics on October 8, 2013. This press release announcing the event came

from CERN, the European Organization for Nuclear Research.

CERN experiments observe particle consistent with long-sought Higgs boson
4 Jul 2012

Geneva, 4 July 2012. At a seminar held at CERN today as a curtain raiser to the year's major particle physics conference, ICHEP2012 in Melbourne, the ATLAS and CMS experiments presented their latest preliminary results in the search for the long sought Higgs particle. Both experiments observe a new particle in the mass region around 125-126 GeV.

"We observe in our data clear signs of a new particle, at the level of 5 sigma, in the mass region around 126 GeV. The outstanding performance of the

LHC and ATLAS and the huge efforts of many people have brought us to this exciting stage,” said ATLAS experiment spokesperson Fabiola Gianotti, “but a little more time is needed to prepare these results for publication.”

“The results are preliminary but the 5 sigma signal at around 125 GeV we’re seeing is dramatic. This is indeed a new particle. We know it must be a boson and it’s the heaviest boson ever found,” said CMS experiment spokesperson Joe Incandela. “The implications are very significant and it is precisely for this reason that we must be extremely diligent in all of our studies and cross-checks.”

“It’s hard not to get excited by these results,” said CERN Research Director Sergio Bertolucci. “We stated last year that in 2012 we would either find a new Higgs-like particle or exclude the existence of the Standard Model Higgs. With all the necessary caution, it looks to me that we are at a branching point: the observation of this new particle indicates the path for the future towards a more detailed understanding of what we’re seeing in the data.”

The results presented today are labelled preliminary. They are based on data collected in 2011 and 2012, with the 2012 data still under analysis. Publication of the analyses shown today is expected around the end of July. A more complete picture of today’s observations will emerge later this year after the LHC provides the experiments with more data.

The next step will be to determine the precise nature of the particle and its significance for our understanding of the universe. Are its properties as expected for the long-sought Higgs boson, the final missing ingredient in the Standard Model of particle physics? Or is it something more exotic? The Standard Model describes the fundamental particles from which we, and every visible thing in the universe, are

made, and the forces acting between them. All the matter that we can see, however, appears to be no more than about 4% of the total. A more exotic version of the Higgs particle could be a bridge to understanding the 96% of the universe that remains obscure.

“We have reached a milestone in our understanding of nature,” said CERN Director General Rolf Heuer. “The discovery of a particle consistent with the Higgs boson opens the way to more detailed studies, requiring larger statistics, which will pin down the new particle’s properties, and is likely to shed light on other mysteries of our universe.”

Positive identification of the new particle’s characteristics will take considerable time and data. But whatever form the Higgs particle takes, our knowledge of the fundamental structure of matter is about to take a major step forward.

Footnote(s)

1. CERN, the European Organization for Nuclear Research, is the world’s leading laboratory for particle physics. It has its headquarters in Geneva. At present, its Member States are Austria, Belgium, Bulgaria, the Czech Republic, Denmark, Finland, France, Germany, Greece, Hungary, Italy, the Netherlands, Norway, Poland, Portugal, Slovakia, Spain, Sweden, Switzerland and the United Kingdom. Romania is a candidate for accession. Israel is an Associate Member in the pre-stage to Membership. India, Japan, the Russian Federation, the United States of America, Turkey, the European Commission and UNESCO have Observer status.

Pauling, Linus “Carl” (1901–1994)

A Nobel Prize-winning chemist and peace activist, Linus “Carl” Pauling was also a biochemist and an educator who published over 850 science-related books and helped found the fields of quantum chemistry and molecular biology. Born on February 28, 1901, in Portland,

Oregon, Pauling had one sister. Amazed at what combining different substances could do, the young man developed a passion for chemistry. He later quit a job as a machinist to pursue a university education.

Despite his parents’ belief that his current occupation was sufficient, the 16-year-old Pauling applied to Oregon Agricultural College in Corvallis, Oregon,

where he received his bachelor's in chemical engineering in 1922 while also working full time at a variety of jobs to pay his own tuition, since his parents would not. He then pursued a PhD at the California Institute of Technology (Caltech) in chemistry and mathematical physics, which he earned in 1925, just three years after his first degree.

A year later, he earned a Guggenheim Fellowship that allowed him to spend two years studying under a series of European physicists focused on quantum mechanics. When he returned to the States, Caltech hired him to teach theoretical chemistry. Four years later, the American Chemical Society granted him their Langmuir Prize celebrating significant work in pure science done by a chemist under the age of 30.

A friendship with fellow professor Robert Oppenheimer soured after Oppenheimer flirted openly with Ava Helen Miller, the human rights activist who had married him in 1923. The marriage lasted; the friendship with Oppenheimer did not.

In 1932, Pauling created the Pauling Electronegativity Scale, which predicts the nature of bonds between atoms in molecules and is still in use today. Likewise, he created the concept of orbital hybridization, which described different ways that electrons in molecules bond.

Despite their estrangement, at the start of the Manhattan Project during World War II, Oppenheimer invited Pauling to join the team to lead the chemistry division, but Pauling declined in favor of working for the military on a broader series of projects. For them, he invented the Pauling oxygen meter to measure oxygen conditions in submarines and airplanes. At the same time, due to his wife's influence, Pauling joined the Emergency Committee of Atomic Scientists created and chaired by Albert Einstein to warn the public of the dangers associated with the development of nuclear weapons. For this and other contributions to safety for soldiers, Pauling was awarded a Presidential Medal for Merit by President Harry S. Truman in October 1948.

Based on the completion of his groundbreaking textbook *The Nature of the Chemical Bond*, Pauling received the Nobel Prize in Chemistry in 1954. But his attention after the war turned to advocating for peace. He wrote a stream of letters to politicians and other people of influence voicing concern over the use of

nuclear weapons and promoting nuclear disarmament. He also published books on the subject of peace and participated in debates around the country. The work that Pauling, Miller, and their fellow peace advocates did resulted in John F. Kennedy and Nikita Khrushchev signing the Partial Test Ban Treaty of 1963. That year, the Nobel Prize Committee awarded Pauling the Nobel Peace Prize for 1962.

Not only was Linus Pauling an accomplished scientist and a peace activist, he was a husband and a father. Pauling and Miller had four children who all grew up to be involved in the sciences, from psychiatry to biology and geology. Pauling passed away August 19, 1994, from prostate cancer.

Permanent Press Fabric

Winner of the Lifetime Achievement Award, Ruth Benerito is credited with saving the cotton industry through her invention of permanent press fabric while working for the U.S. Department of Agriculture in the 1950s. Ruth Benerito was a prolific chemist and inventor who was granted a total of 55 patents. She was awarded membership in the National Inventors Hall of Fame for her contributions to science and education. In the early years of her career, she invented permanent press cotton by attaching organic chemicals to cotton fibers. Her patented process helped start a revolution in the fabrics industry.

Benerito was born Ruth Mary Rogan on January 12, 1916, in New Orleans, Louisiana, to Bernadette and John Edward Rogan, who both advocated for

women's liberation. Benerito graduated from high school in New Orleans at the age of 14 and enrolled in H. Sophie Newcomb Memorial College at Tulane University at the age of 15. She received her bachelor's degree in chemistry in 1935, during the Great Depression. Due to the scarcity of employment, she took a position at Jefferson Parish High School as a teacher of math, science, and driver's education while also attending night classes at Tulane until receiving her master's degree in physics in 1938.

Benerito then taught college classes at Tulane University while using summer and other school leaves to complete her doctorate in physical chemistry from the University of Chicago in 1948. She married Frank Benerito in 1950 and soon after went to work at the U.S. Department of Agriculture's Southern Regional Research Laboratories in New Orleans. Benerito worked at the USDA for most of her career and was granted a total of 55 patents, the most notable of which was her process for creating permanent press cotton fabric, and the creation of stain- and fire-resistant fabrics has been attributed to her as well. Her husband, Frank, died 20 years after they married.

With the 1930s and 1940s inventions of nylon and polyester, fibers that did not need pressing, the cotton industry suffered a catastrophic blow that left it in rapid decline. In the 1950s, Benerito's research team at the USDA identified the fragility of the hydrogen bonds in cotton that led cotton fabrics to wrinkle easily. Benerito and her team overcame the issue by treating the fibers with formaldehyde and other organic chemicals to replace the weak hydrogen bonds with a synthetic "cross-linking." This process was later refined by Benerito and others to be more environmentally friendly and more user-friendly. Cotton saw a resurgence in fashion by the 1990s.

Benerito dedicated the majority of her life to teaching until retiring in 1997. She died in 2013 at age 97.

Petroleum Industry (Post–World War II)

Despite significant resources in states like California and Texas, following the end of World War II, the United States became increasingly dependent on oil from foreign sources. The vast scale of industrial production in the United States, combined with the affordability of the automobile for huge numbers of American consumers, meant that American demand for oil was progressively outpacing current domestic supply, and other nations, like Mexico and Venezuela, could produce oil more cheaply. U.S. oil companies operated in the Middle East with the agreement of host nations, reaping enormous profits, and the U.S. government worked to secure foreign oil supplies.

In 1953, the United States (along with Britain) covertly overthrew Prime Minister Mohammad Mossadegh of Iran due to fears that Mossadegh was moving the country (and its vast oil holdings) toward support of the Soviet Union. By the end of the decade, small domestic producers were increasingly unable to compete with large multinationals operating in foreign countries. The Eisenhower administration instituted quotas on imported oil to protect small producers (though the United States was still largely dependent on foreign oil for a large percentage of its oil use). The quotas infuriated oil-producing nations throughout the next decade.

The U.S. dependence on foreign oil came into visceral focus for Americans in the 1970s. In October 1973, when the United States was discovered to be providing covert support to Israel in the Yom Kippur War against Egypt, the oil-producing countries of the Middle East instituted a graduated cutback of oil exports to the United States as punishment. Long lines appeared at gasoline stations across the country, with irate drivers getting into shouting matches and even fistfights with each other as they waited (sometimes

for hours) to buy the gasoline essential to completing their daily routines. President Richard Nixon instituted price controls on oil produced domestically to try to keep gasoline prices down, but he could do little about the price of imported oil, which rose steadily throughout the fall. Because American oil companies drilling in the Middle East split profits with the host governments, the retaliatory price increases caused American oil companies operating in the Middle East to see their profits balloon. The American public became enraged upon hearing that oil companies had reaped massive profits while consumers suffered.

The embargo caused redoubled efforts to increase domestic oil production. In the late 1960s, the oil company Atlantic Richfield had confirmed the existence of a significant oil field in the Prudhoe Bay area on Alaska's North Slope. Yet the emerging environmentalism of these years, combined with a general distrust of large institutions after the Vietnam War and Watergate, made it difficult to muster the political will to build the 800-mile-long pipeline to bring the oil to the southern coast. (The northern waters contained too many icebergs to send tankers directly to the oil field.) It was only after the embargo and the resulting anxieties about energy security that the pipeline was approved in Congress, and it passed by the slimmest of margins, with Vice President Spiro Agnew breaking a tie in the Senate.

Five major oil companies agreed to share construction costs and ownership, but the pipeline itself represented a massive engineering project. Long sections of the pipeline were set high above the ground, as the natural heat exuded by crude oil would melt the Alaskan permafrost. But other sections had to be buried so as not to disturb caribou migration routes, which necessitated heavy insulation. The pipe was built in a zigzag pattern to absorb the shrinking and expanding caused by the heat of the oil, and extreme zigzags were added in the Denali area to compensate for potential seismic activity. Though the pipeline has been safely transporting crude oil across Alaska for decades, the 1989 *Exxon Valdez* oil spill in Prince William Sound damaged its environmental legacy.

After the end of the 1973 oil crisis caused immediate fears to dissipate, American consumption patterns quickly returned to normal. Jimmy Carter, a former nuclear engineer elected to the presidency in 1976,

attempted to encourage conservation to achieve a lasting reduction in aggregate energy consumption. However, Americans who had become accustomed to large cars and comfortable daily routines resisted admonitions to change their way of life, demanding that the government solve the problem instead. And in late 1978, protests against Iran's ruling shah paralyzed the country, forced the evacuation of Western expatriates working in Iran's oil industry, and caused world oil prices to spike again. Revolutionary Iranians believed that the shah was exporting the nation's oil wealth to the West, and they replaced him with the religious fundamentalist Ayatollah Khomeini.

Carter's response to this second energy crisis took multiple forms. First, he created the Synthetic Fuels Corporation in 1980, which provided federal subsidies to oil and gas companies for commercial production of synthetic fuel (liquid fuel obtained through chemical reactions from sources such as coal). Carter also moved to eliminate the price controls on domestic crude oil that had been instituted earlier in the 1970s. Raising the price, he thought, would force Americans to use less oil and embrace conservation and alternative sources instead. But Carter was worried that oil companies would use the increased profits resulting from decontrol to buy hotels and department stores, and so, alongside decontrol, he instituted a "windfall profits" tax to reinvest oil revenues into alternative energy research.

Oil companies strongly supported decontrol but opposed the tax on increased revenues. High-ranking oil executives testified in Congress that the tax would inflict immense damage to the industry. Pointing to the complex challenges presented by the Alaska pipeline's construction, they argued that future domestic discoveries would almost certainly be found in similarly remote and inhospitable places (such as the ocean floor) and would require vastly greater investment in exploration and construction than had the easy discoveries of past decades. Carter rejected the industry's argument and instituted the tax, though his successor Ronald Reagan repealed it soon after taking office in 1981. The uncertainty caused by the multiple oil crises in the 1970s helped decrease American demand for oil, which led global prices to drop in the early 1980s, and the Synthetic Fuels Corporation was abolished in 1985 on the grounds that it was no longer needed.

The latter years of the 20th century (and the first of the 21st) witnessed mergers in the oil industry that created some of the most valuable companies in the world. In 1984, Standard Oil of California merged with Gulf Oil (the largest merger in history at that point) to create Chevron. Chevron acquired Texaco in 2000 and the Unocal Corporation in 2005. In 1999, Exxon and Mobil merged to create ExxonMobil, which in 2014 was the third-largest company in the world. The second-largest, the Anglo-Dutch oil company Shell, trailed only Walmart.

The petroleum industry's environmental impact, which had been criticized in 1969 with an oil spill off the coast of Santa Barbara and again in 1989 with the *Exxon Valdez* spill, came under even more intense scrutiny in April 2010. An offshore oil rig in the Gulf of Mexico experienced a blowout when high-pressure methane gas from the underwater well rose into the drilling rig, where it ignited and exploded. Oil gushed from the damaged well, and the equivalent of over 4 billion barrels of oil were released into the Gulf. The spill caused significant damage to the shrimping and tourism industries on the Gulf Coast and generated intense criticism from the U.S. government and the press.

Another major environmental controversy had to do with the proposed Keystone XL pipeline. The XL portion was a prospective addition to an existing system that already carried oil from Alberta to the Gulf Coast, but the XL project would run over delicate sand dunes in Nebraska as well as the Ogallala Aquifer, a major source of drinking water. In early 2012, President Barack Obama rejected the XL proposal, citing environmental concerns. Although Nebraska's governor approved a revised plan in early 2013 designed to minimize impact on the dunes and aquifer, the Obama administration announced an indefinite extension of the federal review process in the spring of 2014. Because the decision came alongside strict new rules on carbon emissions, the administration's decision was likely based not on the pipeline's physical impact on the land but on broader concerns about the long-term environmental sustainability of fossil fuel use.

The 21st century also brought an oil boom to the state of North Dakota, which sits atop a rock formation known as the Bakken, which is composed of sedimentary rock from which oil can be produced. Oil was first

discovered within the Bakken formation as early in 1951, but for decades the cost of retrieving it from the ground was prohibitive. Two technologies made harvesting the shale oil cost-effective by 2000: hydraulic fracturing (injecting high-pressure liquid into a well-bore to create small cracks and allow the petroleum to move to the well) and slant drilling (which allows oil wells to be drilled at nonvertical angles. Despite the nationwide economic crisis that began in 2008, North Dakota experienced an economic explosion, with developers unable to keep up with the housing needs of the massive inflow of workers and the government unable to build enough schools for their children.

Plasma Arc Welding

Plasma arc welding (PAW) is an advanced welding system that allows the welder the accuracy necessary to weld both thin and thick metals. This precision results in more advanced welding capabilities and techniques. Welding precision, along with PAW's reliability, have revolutionized the welding industry ever since the system hit the market.

Robert M. Gage introduced plasma arc welding in 1954 and ultimately patented his invention in 1957. However, it was not until 1964 that Gage's welding device was brought to the market. PAW uses plasma gas, which is an ionized gas and considered to be a fourth state of matter because of its unique capabilities. PAW is similar to gas tungsten arc welding; however,

in plasma arc welding, the plasma is forced through a copper nozzle, which results in the gas coming out at a much higher temperature compared to gas tungsten arc welding. During welds, the arc in the welding system can reach temperatures up to 33,000°C. The PAW system includes a plasma torch, voltage control, current control, high-frequency generator, and shielding gases.

During the welding process, the system uses plasma gas to transfer an electric arc to the metals being worked on. Because of the heat of the arc, the metals being welded bind and fuse together. The PAW system transfers an intense heat to a small, concentrated area, leading to more accurate welds.

When working with plasma arc welding, weld times can be as short as five milliseconds, and the system is even stable at low amps. Additionally, PAW sports a protected electrode, which allows for less contamination and results in cleaner welds. The system's versatility allows it to be used for welding anything from kitchen appliances and surgical instruments to jet engine blades and automobile chassis. Also, due to PAW's long electrode life, the system can be used in high production situations. Plasma arc welding can also be used in cutting applications. During plasma cutting, the plasma gas needs to be increased so it can result in deeper penetration of the metal being cut.

Today, plasma arc welding is still one of the most popular welding systems. Over the years, the PAW system has received minor but significant improvements. The modern system is still a favorite among welders, and it is used across various industries.

Plastics

Plastics are a subset of polymer materials and have a wide range of composition from organic to fully synthetic compounds. Plastic is known for its light weight, high malleability, and high moldability. Malleability is a material's ability to deform under stress without fracturing, thus allowing plastic to be hammered or rolled into thin sheets. Synthetic plastics are commonly derived from petroleum, while semisynthetic or nonsynthetic plastics can derive from cellulose. Due to the low cost of production, ease of manufacture, low density, high toughness, versatility, and other desirable properties, plastics have extensive range of and uses and have displaced a great variety of materials that we used to make products from such as wood, metal, and glass.

Plastics can be separated into two categories based on their chemical composition. Carbon-chain plastics are made of linear hydrocarbon polymer. Polyethylene, PVC, polystyrene (Styrofoam), and PTFE are examples of carbon-chain plastics. The second category, heterochain polymers, consist of not just carbon atoms but oxygen, nitrogen, sulfur, or even aromatic rings in their chains. PET, polyurethane, epoxies, polyester, and nylon are examples of heterochain plastics. Each type of plastic has specific properties, such as density, tensile strength, melting temperature, etc., that need to be considered for its intended application. Plastic have been called "the material of a thousand uses," and they certainly have revolutionized the way the world produces and consumes various products.

Plastics evolved out of the use of rubber made from natural materials such as natural gums, latex rubber, and shellac. However, these rubber products often cannot withstand extreme temperatures. In hot environments, they would become intolerably sticky and tacky to touch. In cold environments, they would become too hard and brittle to work well. The unwanted properties of rubber kept industrial interest in it at bay until a method of curing it was possible.

Charles Macintosh, a frugal Scottish dye maker, found himself with too much naphtha after separating ammonia from tar. In an effort to do something with the naphtha, he immersed some raw rubber in it. To his

pleasure, he had obtained a liquid rubber solution that could be brushed on cloth. In 1821, he started coating canvas with this rubber solution to make a waterproof raincoat called a “mack.”

In the United States, Charles Goodyear was long fascinated with the special properties of rubber and was determined to improve it. Goodyear’s relentless efforts often drove him to bankruptcy and debt. His first moderate success was in treating rubber with nitric acid vapors laced with sulfuric acid, which dramatically improved rubber’s heat resistance on the outside. In 1839, he had a stroke of luck. While working with latex mixed with sulfur, he dropped some on a hot stove. Rather than melting into a goo as any ordinary rubber would, this mixture charred evenly, ending up like a piece of leather. After it was cool enough to scrape off, the new material stayed pliable, even in the winter cold.

Goodyear eventually perfected his new processing method but raised only enough funding to file for an American patent and not a British one. He appointed a young Englishman, Stephen Moulton, to meet with Thomas Hancock and Charles Macintosh in hopes of a joint venture and a British patent. Hancock, seeing the possibility, spent weeks in his lab to tackle the problem himself and came to the conclusion that sulfur was indeed the key. He filed for a British patent just two months before Goodyear did and coined the name for the process: “vulcanization.”

In 1846, a British surgeon practicing in Madagascar noticed a shiny, dark brown material that the natives were selling called “gutta-percha.” Gutta-percha was softened in hot water, pressed by hand, and became rock hard after cooling. Recently expanded international telegraphy lines lacked sufficient insulation to coat submarine telegraph lines, as rubber was not corrosive resistant enough in salt water. Gutta-percha, on the other hand, was resistant to salt and electrical current.

In 1862, Alexander Parkes, an English inventor, made the first man-made organically derived plastic, nitrocellulose. It was made by treating cellulose with nitric acid and a large quantity of castor oil. However, the plastic was not malleable, and the amount and cost of castor oil required was too high for Parkes’s company. Investors decided to pull out. In 1868, American

John Wesley Hyatt improved on Parkes’s nitrocellulose by treating it with camphor instead of castor oil, which did make it malleable. The new plastic could even imitate ivory and tortoiseshell. Hyatt called this improved plastic “celluloid,” and it became the first commercially successful plastic, but it did have a flaw. Camphor is quite flammable, and subsequently it burned a four-story celluloid plant down in just under two hours.

It was not until 1907 that a big breakthrough set the precedent for the first synthetic plastic. Having had much success in 1899 making and selling the new photographic paper called “Velox,” which made developing photographs quick and easy at home, an American immigrant chemist named Dr. Leo Baekeland set his eyes on making viable synthetic resin. Baekeland began investigating the reaction of phenol and formaldehyde and approached the issue systematically, considering temperature, pressure, material, and proportion. After years of research, he found a way to produce a hard, moldable plastic that he called “Bakelite,” and he finally introduced the material to the world in 1909. It took several years—until the 1920s—for the world to fully accept the concept of polymers. But as early as 1927, publicists had proclaimed the Plastic Age of historical significance equal to that of the Bronze, Iron, or Steel Ages.

Plastic had become such an integral part of the world by the 1920s that Baekeland proudly claimed that he could name no more than 43 industries that had no use for his Bakelite at all. By World War II, the plastic industry had expanded so much that baby boomers grew up with them as a major component of their lives and in everything from toys to grocery bags. In the United States, production tripled from 1940 to 1945, and in 1945, 818 million pounds were produced. Most of those plastics went to military uses. New materials and processes were constantly being tested as well. Vinyl polymers were in experimental use, transparent acrylic was a promising alternative as unbreakable “glass,” and the injection-molding process made production cheaper and faster. By 1960, annual production surpassed 6 billion pounds and, 50 years later in 2011, annual production exceeded 600 billion pounds.

In the past, metal, glass, rags, leather, and other materials that we made things from could be scrapped and resold to industry as informal recycling. What could not be used or sold was burned as a source of heat. There was little waste as we think of it today. As early as the 1920s, it became common to throw garbage into landfills. Although packaging required the increasing consumption of plastic, plastic was everlasting and reusable. But the low cost and speed of production made it “disposable.” In the late 1960s and early 1970s, critics warned that disposing of synthetic materials in landfills was an environmental disaster, as they did not degrade quickly. By the 1980s, major U.S. cities began establishing plastic and recyclable collection programs, with Rhode Island becoming the first state to mandate recycling in 1986. In 2011, about 70 percent of plastic scraps in the U.S. were shipped to China for recycling at an estimated worth of \$11.3 billion.

With ever-growing concern for the environment, there has been a push toward plastic that is environmentally friendly, like bioplastic. Currently, there are three main groups of bioplastic. One is bio based and biodegradable, such as polylactic acid and polyhydroxyalkonate, which are derived from natural and renewable resources. Another group of bioplastic that is partially or fully bio based but not biodegradable, such as bio-polyethylene or bio-polyethylene terephthalate (PET) is derived from renewable resources. Last but not least are bioplastics that are fossil fuel based and biodegradable, such as polybutyrate. The move toward bioplastic is to reduce the reliance on nonrenewable resources, but currently, bioplastic is more costly to manufacture, and not all bioplastic can be recycled through conventional methods—or it requires a specific composting process.

Polaroids

In 1948, Edwin Land invented the Polaroid camera and revolutionized photography, allowing photos to be seen shortly after they were taken.

After graduating from Harvard, Land founded the Polaroid Company in 1937, locating the facility near Harvard and MIT to attract top talent. A team of 37 joined his initial project of adding polarizers to auto headlights to reduce the glare of oncoming traffic. Although many car companies expressed interest in this new feature, they were reluctant to invest. The rejection almost caused the company to fail.

World War II helped Polaroid recover quickly, and it shifted production to support the war effort. The company helped develop planes capable of taking aerial photographs and then putting those photos onto a special film with polarizing dyes for better resolution. War work left the company flush with government funds for more diverse research, including film research.

On a family vacation in 1944, Land took a photo of his daughter, who asked why she couldn't see the picture right away. He couldn't provide a reasonable explanation for why that wasn't possible. Thus, when he returned to work, he assembled a team to find a way to make photos appear instantly. In 1946, the company created a silver-image (black-and-white) photograph. A photo appeared moments after capture, shrouded with a negative layer that had to be removed to reveal the image. However, the development process proved difficult, creating unstable photos often accompanied by chemical residue. After enlisting the help of chemists to correct image issues, the first instant Polaroid camera became available for purchase in November 1948. The camera was large and cumbersome, and the first photos were often yellow or brown and unappealing. However, Land had achieved his goal of creating instant photography.

Building on that success, he now wanted to develop instant color photos. To assist in the project, Edwin Land partnered with Kodak. The companies agreed that Polaroid would complete the chemical and process research and Kodak would supply the necessary emulsions to

produce color photographs. In 1963, they succeeded, and Polaroid color film became widely sold, an instant success.

Always striving to improve his product, Land set out to make the Polaroid experience most recognized today: a camera capable of producing a color photo instantly, without the need to remove any layers. That camera was the SX-70, appearing first in 1972. SX-70s sold rapidly, and by 1973, about 5,000 cameras were manufactured and sold daily.

Despite the achievements and the dedication to innovation of Land and Polaroid, the success of the camera was short-lived, peaking in the 1970s and decreasing during the 1980s and 1990s. Technological advancement and the introduction of digital and cell-phone cameras diminished the phenomenon of the Polaroid. To adapt, Polaroid continues to create updated versions of the Polaroid camera sold at many large retailers, connecting past to present and securing Polaroid's place in the technological world.

Polio Vaccine

Polio vaccines were developed in the 1950s to resist poliomyelitis (or, commonly, "polio") by means of immunization and preventative medicine. Polio reached pandemic proportions in the first half of the 20th century, and the campaign to discover and propagate the vaccine was seen as one of the triumphs of modern American medicine. The application of these vaccines has nearly eradicated the disease and dramatically lowered its presence globally. The polio vaccine remains on the World Health Organization's List of Essential Medicines, which outlines medical items necessary for establishing the most basic standard for medical care worldwide.

Polio is an infectious disease that causes muscle weakness and paralysis. It most commonly affects leg muscles but can affect the arms, torso, and neck as well. The adult mortality rate for polio is upward of 30 percent, while for children it is 2 to 5 percent. Some polio sufferers recover entirely, while others suffer from muscle weakness and paralysis for the rest of their lives. The polio virus is spread through fecal matter ingestion, making the disease particularly problematic in developing nations. The polio vaccine is effective at stopping the disease, though currently the Centers for Disease Control recommends that persons who have been vaccinated get a booster shot before traveling to countries experiencing polio outbreaks.

The first clinical assessment of polio dates to 1789 and was composed by the English physician Michael Underwood. However, polio as a viral disease can present a wide range of symptoms (or indeed, no symptoms at all) and has existed since the earliest recorded civilizations. The minority of cases (somewhere around 1 to 2 percent) result in the virus entering the nervous system and spinal cord, causing paralysis and physical deformity.

Such a variety of symptoms and victims meant that polio was difficult to discretely diagnose, and it wasn't until the late 19th century that the combined efforts of German physician Jakob Heine and Swedish pediatrician Karl Oscar Medin led to the identification of polio as Heine-Medin disease, or "infantile paralysis." During the 20th century, the incidence of polio shifted from infants to children and young adults, whose age group as a whole had a greater chance of paralysis from the virus. In 1952 and 1953, the United States witnessed a surge of polio cases at nearly twice the yearly average. Such alarming numbers prompted public organizations and private laboratories such as Lederle Laboratories in New York and the University of Michigan Poliomyelitis Vaccine Evaluation Center to seek out a preventative vaccine.

A number of early experiments to create a polio vaccine failed to achieve positive results. In 1936, Maurice Brodie attempted to fashion a vaccine from attenuated (reduced in virulence) polio retrieved from the spinal cords of experimental monkeys. He administered this vaccine to several thousand children without conclusive results. A later experiment by pathologist

John Komer in Philadelphia was later blamed for some children contracting the disease. In 1948, John Enders successfully grew polio virus from human tissue in laboratory conditions. Such developments in replicating polio furthered vaccine research by providing a thorough understanding of the workings of the virus and its development within the human body.

The first polio vaccine was developed in 1952 by Jonas Salk, an American virologist and physician working at the University of Pittsburgh. Salk's vaccine was derived from three strains of polio raised in the kidney tissue of a monkey and rendered innocuous with formalin, a variety of formaldehyde. With the pitfalls of the previous attempts at a polio vaccine in mind, Salk and his collaborators submitted his vaccine to a long period of clinical trial and testing. Salk's test runs on children started in 1953 and were heavily advertised in print media and broadcast on radio as a public relations tool. At its height, nearly 1.8 million children were involved in the experiment, and it was found to be 60 to 70 percent effective with polio type 1 and over 90 percent effective with strains 2 and 3. In 1955, a campaign of vaccination propagation occurred in the United States that aided in the lowering of polio cases to 161 by 1961. Salk received the Lasker Award for his work in immunology in 1956 and the Presidential Medal of Freedom in 1977.

Oral polio vaccines were also instrumental in lowering the instances of polio in the late 20th century. The oral vaccine is derived by passing a live strain of the virus through nonhuman cells, which in turn produces a weakened mutation.

Polish-born immunologist and virologist Hilary Koprowski claimed that he discovered the first polio vaccine while working at Lederle Laboratories in 1950. Koprowski's live, oral vaccine, however, was not out of research and testing before Salk presented his discovery to the world. Groups of clinical experimenters worked on an oral vaccine throughout the 1950s, but it was the strain discovered by Albert Sabin that would be adopted by the National Institutes of Health in 1958. The Sabin vaccine was easier to administer than Salk's and offered a longer immunity.

The World Health Organization announced in 1988 its intention to eradicate polio much as it had eradicated smallpox in the 1970s. The primary tool for

the WHO is variations of the Sabin vaccine. The last case of an endemic transmission of polio in the United States occurred in 1979 among Amish communities in the Midwestern states. Despite its great rarity in the United States and the developed world, "wild" polio-myelitis continues to occur in Africa and Asia in places without access to clean water or sanitation.

Pong

Pong is arguably the first video game to reach masses of people. Atari, an American video game company founded by Nolan Bushnell and Ted Dabney, created and released the two-dimensional ping-pong game in the summer of 1972.

The game was not initially intended for commercial release, as it was merely a training exercise for Alan Alcorn, a prospective employee who had just been hired by Atari. Alcorn was asked to create a table-tennis game that needed two paddles, a playing field for the ball to move freely on, and digits to show the score. Alcorn tweaked the game so the ball could bounce around at the angles and sides of the screen. He also made the ball bounce back and forth faster with each consecutive hit. Atari cofounder Nolan Bushnell supervised the *Pong* project and worked with Alcorn through its development. Bushnell felt that the game needed realistic sounds, such as that of a crowd, to be featured in the game. Alcorn found a way to bring them. When Alcorn fit all the major components into a wooden cabinet, Bushnell and Dabney envisioned the commercial possibilities of selling such a product.

The video game was installed at a local bar to test its favorability with consumers. Customers loved it so

Though *Pong* was first developed as an arcade game, Atari made a home use version in 1975. The *Super Pong* console, seen above, remains a gaming icon. (Sascha Steinbach/Getty Images)

much that the only problem with the game was that too many quarters were being inserted to the machine, creating technical issues. It was then that Atari decided to manufacture *Pong* at a greater scale.

The game of *Pong* made its way into living rooms around the world when Atari began developing home consoles that could plug into television sets, such as the Atari 2600. Atari signed a contract with Sears in 1975 that dubbed the Atari 2600 “Home Pong.” Sears sold nearly 150,000 units that holiday season alone.

Bushnell felt that the only way to keep up with competitors was to create sequels. Over the years after *Pong*’s initial launch, the Atari team created sequels such as *Pong Doubles*, *Super Pong*, and *QuadraPong*.

Portable Transistor Radio

Following the 1947 development of the transistor, Texas Instruments (TI) and Industrial Development Engineering Associates (IDEA) introduced the world’s first commercially available transistor radio, the Regency TR-1. While this first portable radio was mainly a novelty item, other portable radios based on

transistor technology flooded the market in the 1960s and 1970s.

Portable radios fundamentally changed American musical culture and American listening habits. Post–World War II economic affluence meant that many people could afford the small radios. Untethered from large, in-cabinet home radios, people could carry their music and news with them. Young people bought the small radios (or had them bought by affluent parents). Away from their homes and parental control of the family radio, young Americans could listen to music of their choosing. Popular music exploded as music production companies began to cater to the tastes of American youth.

By the late 1980s, portable tape players like the Sony Walkman largely replaced portable radios. Portable CD players and iPods followed, and each innovation made the portable radio more of a historical artifact.

Rocket Girls of JPL

The “Rocket Girls” of NASA’s Jet Propulsion Laboratory (JPL) were human “computers” who calculated the trajectories of rockets and created many computer programs with the FORTRAN programming language starting in the 1940s. The group was led by supervisors Macie Roberts and Helen Ling, who were inclined to hire only women due to a cultural way of thinking that men would be uncomfortable taking direction from women. There was also a stigma that the tasks that they were generally responsible for were considered “women’s work” by most, including their colleagues and the engineers above them.

This trend of an all-female group continued up to and through the 1960s before the advent of more powerful electronic computers in the 1970s that made the plotting of mission trajectories much simpler. After the introduction of these supercomputers, the need for

complex mathematical plots to be done by hand decreased, and the desire for more complex computer software increased. But these women were the first programmers at NASA.

Many of the Rocket Girls held degrees or were otherwise deeply skilled in mathematics. These female “computers” were pivotal to many of NASA’s missions, including the Explorer-1 mission that put the first U.S. satellite into Earth’s orbit and the unsuccessful Ranger missions one through six. They ultimately succeeded at landing (crashing) a spacecraft on the moon with the Ranger-7 mission and were successful at relaying data and photographs 1,000 times better than what was obtainable from the surface of the earth. During the time of the Ranger missions, the JPL set its sights beyond the moon and had sent similar spacecraft to collect data from Mercury, Mars, and Venus.

Of the many women designated as Rocket Girls at JPL, Eleanor Francis Helin is one of the most highly recognized. Helin was inducted into the Women in Science and Technology International (WITI) Hall of Fame in 1998, earning this after more than 30 years of hard work at the California Institute of Technology and at JPL. Helin’s accomplishments were many and included numerous asteroid discoveries and her role as the principal investigator for the Near Earth Asteroid Tracking (NEAT) program responsible for discovering more than 26,000 objects, including 30 near-earth asteroids, under the guidance of NASA, JPL, and the U.S. Air Force. Helin was also the recipient of NASA’s Exceptional Service Award and the 1997 JPL Award for Excellence due to her role in the NEAT program. Helin retired in 2002 and passed away in January 2009. In 1987, Edward Bowell named an asteroid after her, using her nickname Glo. Approximately 6 miles in diameter, 3267 Glo is a Mars crossing asteroid.

Other Rocket Girls of notable accomplishment include Linda Lee, who took JPL’s trajectory analysis from a mission that was to rendezvous with Halley’s comet and created one of the mission’s earliest computer animations. Lee is currently responsible for developing command and sequencing software. As of 2018, Susan Finley, who hand plotted the Ranger mission trajectories, was still with JPL working as a testing engineer and was involved in developing software for the Mars Science Laboratory Mission. Helen Ling

was yet another notable software developer and created programs used in many of the missions during her time at JPL, including the Infrared Astronomical Satellite, Magellan, Mars Observer, and Topex/Poseidon. Ling's software development skills left a lasting impression on the Voyager Mission designer, Charley Kohlhasse, who did not allow anyone else to work on his software. Helen Ling retired in 1994 to Pasadena, California, with her husband, Art.

When we try to reach another astronomical body, whether we are putting a human being on it or just a rover, it is important to do so as efficiently as possible. The Rocket Girls quickly discovered that launching a craft carrying a large ordnance of fuel when two planets are relatively close in orbit is not the best strategy. The contributions made by JPL's Rocket Girls are far-reaching and will have repercussions for many years to come. These women deserve credit for helping to land the first human on the moon and every subsequent mission since the 1940s. Their contributions will have an impact on every future mission as humans continue to explore the unknown, land a crew on Mars, and continue to search for signs of intelligent alien life in the universe.

FOR IMMEDIATE RELEASE June 24, 1998

ASTEROID FINDER NAMED TO WOMEN IN TECHNOLOGY HALL OF FAME

Asteroid finder and astronomer Eleanor F. Helin of NASA's Jet Propulsion Laboratory, Pasadena, CA, has been named to the Women in Science and Technology International (WITI) Hall of Fame, an award that honors women in science and technology worldwide.

Helin will be honored at ceremonies to be held Thursday, June 25, at 7 p.m., during the WITI 1998

Technology Summit in Santa Clara, CA. The largest-ever conference of top women in technology, the WITI 1998 Technology Summit will draw more than 3,500 technologists and scientists from around the world. WITI Hall of Fame was launched in 1996 to recognize, honor, and promote the outstanding contributions women make to the scientific and technological communities and society at large. Inductees are chosen by an independent panel of judges.

Donna Shirley, manager of JPL's Mars Exploration Program, was inducted into the WITI Hall of Fame last year, and is a featured speaker at Thursday's ceremonies.

Helin has been active in planetary science and astronomy for more than three decades at the California Institute of Technology and JPL, a division of Caltech managed for NASA. She is the principal investigator for the Near Earth Asteroid Tracking (NEAT) program, a collaborative effort of NASA, JPL and the U.S. Air Force which has already detected more than 26,000 objects including 30 near-Earth asteroids.

In the early 1970s, Helin initiated the Palomar Planet-Crossing Asteroid Survey from Caltech's Palomar Observatory in Southern California, resulting in the discovery of thousands of asteroids of all types including 100 near-Earth asteroids and 20 comets. One of the most significant discoveries was that of asteroid 2026 Aten, the first asteroid found to have an orbit smaller than the Earth. Another of her asteroid discoveries, KD 1992, was recently named the new target for a flyby to be conducted in July 1999 by the NASA/JPL Deep Space 1 spacecraft, due for launch this November.

Helin is a recipient of NASA's Exceptional Service Medal and the 1997 JPL Award for Excellence for her leadership of the NEAT program. The International Astronomical Union named asteroid 3267 Helin in her honor. Helin and her husband reside in Thousand Oaks, CA.

Rogallo, Francis Melvin (1912–2009)

Francis Rogallo was an inventor, aeronautical engineer, flight pioneer, husband, and father. His best-known contribution was the creation of the flexible wing (also known as the Rogallo wing), which was a precursor to what became the hang glider, the paraglider, and led to sport parachuting and stunt kite flying.

He was born in Sanger, California, on January 27, 1912, to Mathieu Rogallo and Marie Dajas Rogallo Betzold. In 1928, he graduated from Sanger High School and later attended Stanford University. In 1935, he received a degree in Mechanical Engineering and Aeronautics.

In 1936 in Hampton, Virginia, he joined the National Advisory Committee for Aeronautics (NACA), which later became the present-day National Aeronautics and Space Administration (NASA). In 1939, he married Gertrude Sudden Rogallo. She was a young educator from Hampton Roads. They were married for over 68 years and together, they raised four children.

Gertrude stayed busy as a housewife while her husband worked as an aeronautical engineer in the

NACA wind tunnels. At home, they worked on creating a vehicle to make flight available and affordable to everyone. While they actively pursued this passion, they met Orville Wright, who further fueled their creative spirits. Francis Rogallo had several patents through his work at NACA, but he was proudest of the flexible kite patent that was coinvented by his wife. This device that was built during their leisure time at home was one of the simplest airfoils ever made. It had no stiffeners and effortlessly created lift and carried payloads.

The couple was recognized worldwide because of their contributions to sport aviation. Together, they received honors from Australia, Japan, Switzerland, Germany, and France. Francis Rogallo also received honors individually in the United States. Francis and Gertrude Rogallo were also inducted into the Paul Garber Shrine at the Wright Brothers National Memorial, where their portrait still hangs. Francis Rogallo was inducted into the North Carolina Sports Hall of Fame and the Public Education Hall of Fame of the California School Boards Association. The couple are both honored with a pylon at the Century of Flight Monument located in Kitty Hawk, North Carolina.

In 1967, they moved to the outer banks of North Carolina, where they attended local aviation group meetings and gliding events. Rogallo joined the First Flight Society, Civil Air Patrol, and the Volunteer Fire Department of the Southern Shores.

Rogallo passed away in his home on September 1, 2009, at the age of 97. His influence on flight was so significant that the wings of hang gliders were widely known as Rogallo wings. Members of the Hang Gliding and Paragliding Association, to this day, are called “Rogallo members.”

Sabin, Albert B. (1906–1993)

Pioneering medical researcher Dr. Albert B. Sabin developed the oral live-virus polio vaccine, the vaccine of choice in most countries. Sabin’s vaccine is widely credited with eradicating polio virtually worldwide.

Sabin was born in Bialystok, Poland, in 1906 and immigrated to the United States with his family in 1921 to avoid religious persecution. After receiving his MD from New York University in 1931, Sabin began research at Bellevue Hospital, and his first polio-related article was published in 1933. Sabin joined the staff at the Rockefeller Institute in New York City in 1935, where he conducted research and first became interested in live-virus vaccines.

In 1939, Sabin took a position as associate professor of pediatrics and research fellow in virology at the University of Cincinnati College of Medicine’s Children’s Hospital Research Foundation. There, he

developed innovative approaches to understanding polio and preventing outbreaks. Although polio primarily affects the nervous system and can grow in nerve tissue, the virus also lives in the small intestine. Sabin presented the medical world with the concept of enteroviruses—viruses that live in the digestive system. He theorized that an oral vaccine might thereby be effective against this intestinal virus.

During World War II, Sabin served on the U.S. Army Epidemiological Board’s Virus Committee, working in Europe, Africa, the Middle East, and the Pacific. He identified the virus that caused sandfly fever and developed vaccines for encephalitis and dengue fever.

Sabin returned to his research on the polio virus after the war. He isolated an attenuated polio virus, a form of the polio virus that was unable to cause the disease. This weakened virus was safe to introduce into the body but could still provide protection by reproducing in the intestines and displacing the lethal forms of the polio virus. Sabin and his research associates were the first experimental subjects, followed by 30 volunteer inmates at a federal prison.

From 1957 to 1959, the oral vaccine was tested outside the United States. Because the Salk polio vaccine was already in use in the United States, researchers were concerned about possible interference in the results due to subjects who had already been vaccinated. Despite the Cold War, U.S. and Russian scientists collaborated to vaccinate 10 million Russian children. The vaccine was first available to the public in the United States in 1960 during the “Sabin Oral Sunday” campaign, and in 1961, the vaccine was approved by the U.S. Public Health Service, replacing the Salk inactive virus polio vaccine.

In 1970, Sabin became the president of the Weizmann Institute of Science, and in 1974, he began work as an expert consultant to the U.S. National Cancer Institute. He continued his research at the Medical University of South Carolina and the National Institutes of Health until his retirement in 1986. Sabin died in 1993. Sabin was awarded the National Medal of Science in 1970 and the Presidential Medal of Freedom in 1986.

Oshinsky, David M. 2006. *Polio: An American Story*. New York: Oxford University Press.

Salk, Jonas (1914–1995)

American medical researcher Jonas Salk developed the first successful vaccine against polio. Salk was born in 1914 in New York City to Russian-Jewish immigrants. He graduated with a degree in science from City College of New York in 1933, and he received his medical degree from the New York University School of Medicine in 1939, completing his internship at Mount Sinai Hospital.

In 1942, Salk accepted a position as research fellow at the University of Michigan, where he later became assistant professor of epidemiology. Beginning in 1943, his focus was on developing a killed-virus influenza vaccine, work that was largely supported by the U.S. Army. The killed-virus vaccine could not cause the disease but nevertheless was able to prompt the body’s immune system to produce antibodies that would prevent it.

As the director of the Virus Research Laboratory at the University of Pittsburgh School of Medicine, Salk began developing a vaccine for polio in 1947. This research was funded by the National Foundation for Infantile Paralysis (now known as the March of Dimes Birth Defects Foundation). The first step of the process was to sort the 125 strains of the virus. Salk identified three basic types of polio virus, which determined the number of strains that would need to be included in the vaccine. The polio vaccine would be a killed-virus vaccine like the influenza vaccine Salk had developed, because even though this approach was contrary to established scientific thought, Salk believed that it would be less dangerous.

In 1952, Salk began experimental trials of the vaccine, first administering it to himself, his wife and children, and his laboratory scientist. He followed those experiments with trials on children who had already contracted polio and found that their antibody

levels increased significantly. These results were published in the *Journal of the American Medical Association* in 1953, and a year later, a double-blind clinical trial was conducted on 1.8 million Americans, mainly children aged six to nine, who came to be known as “Polio Pioneers” in what was the largest public health experiment in American history. When the trial was found to achieve a 60 to 70 percent prevention rate, the vaccine was declared to be safe and effective in 1955.

When asked by CBS news correspondent Edward R. Morrow who owned the patent for the polio vaccine, Salk famously replied, “Well, the people, I would say. There is no patent. Could you patent the sun?” Since the expensive research and field testing had been supported by voluntary public donations to the National Foundation for Infantile Paralysis, he believed that no one person or company should benefit from the vaccine.

The viability of the polio vaccination program was threatened briefly only weeks after its launch. More than 200 children who had recently been vaccinated contracted polio; most became severely paralyzed, and 11 died. The outbreak was traced to inadequate controls at the Cutter Laboratories in Berkeley, California, which had resulted in several lots of the vaccine being contaminated with live polio viruses. Vaccination was temporarily halted by the surgeon general, but this was the only documented case of polio being contracted as the result of the Salk vaccine in the United States.

The polio vaccination effort using the Salk vaccine led to an extraordinary reduction in the number of new cases of polio. In the years between 1950 and 1955, there were between 25,000 and 60,000 cases of polio each year in the United States, while after 1955, there were only a dozen or fewer cases annually. By 1959, 90 other countries were using Salk’s vaccine. However, in 1962, the Sabin oral live-virus vaccine was introduced in the United States on a wide scale, and Salk’s injected killed-virus vaccine was eventually replaced by Sabin’s. Salk’s injected vaccine was eventually reintroduced in the United States in 2000, after Salk’s death, because the live-virus vaccine could cause polio in rare cases. The World Health Organization now recommends that polio-free countries return to using the Salk vaccine.

In 1963, Salk founded the Salk Institute for Biological Studies in La Jolla, California, with a \$20 million grant from the National Science Foundation and support from the March of Dimes. Salk's mission for the Institute was to merge the study of the humanities and the sciences, a mission that he felt was never entirely realized. Here Salk continued research on the immunological aspects of multiple sclerosis, cancer, and AIDS. In his final decade of research, Salk worked on an immunization to forestall the development of full-fledged AIDS.

Satellites and Space Probes

A satellite is an object that orbits a planet or a sun. Man-made satellites have been purposely placed into Earth's orbit. These manufactured satellites are called "artificial" satellites to distinguish them from natural satellites such as Earth's moon, or even Earth itself. A space probe is a robotic spacecraft that does not orbit but follows a trajectory to some destination in space. American space probes have explored the moon, Mars, Mercury, Venus, Saturn, Jupiter, Uranus, Neptune, a variety of comets, and interplanetary space.

Newton's cannonball experiment was the first thought experiment for an artificial satellite. He theorized that a cannonball traveling at a certain speed would be held in Earth's orbit by gravity.

The first artificial satellite to successfully orbit Earth was the Soviet Sputnik 1. It was a metallic sphere about half a meter across, weighing 84 kilograms, and had three long prongs pointing to one side. The satellite stayed in orbit for about six months before falling back to Earth. Its rocket booster, weighing three and a half metric tons, also reached orbit and

was easily visible from the ground. Sputnik helped identify the density of the high atmospheric layers. The second Sputnik satellite was launched on November 3, 1957, and carried a dog named Laika into space. Sputnik 2 was the first satellite to carry a living passenger into orbit.

Space probes and satellites became important during the Cold War, showing how a country's science and space technology could be used to boost patriotism and create fear-based propaganda. The Soviet Union and the United States, in the so-called Space Race, competed for supremacy. The 1969 manned moon landing is often cited as the moment that the United States won the Space Race.

There are three simple classes of nonmilitary satellite services: fixed, mobile, and scientific. Data transmission around the world is handled by fixed satellite services. Mobile satellite systems help connect places with stationary communications units like vehicles and people, as well as serve in navigational systems. Scientific research satellites provide data for different scientific research applications such as earth and marine science, meteorological and atmospheric information, and amateur radio.

There are many different types of satellites. Astronomical satellites are used to observe distant celestial objects. Bio satellites carry living organisms. Communications satellites are positioned in space for the purpose of telecommunication. Recovery satellites provide recovery of many different types of payloads from orbit to Earth. Tether satellites are attached to other satellites by light, thin cables called "tethers." Weather satellites are mainly used to monitor Earth's climate and weather. There are other types of satellites as well.

Space stations are artificial orbital constructs specifically designed for human beings to live in outer space. Space stations are differentiated from spacecraft because they are in stationary orbit and do not have any propulsion or landing facilities. These stations are designed for medium-term living in orbit. The largest artificial satellite currently orbiting the earth is the International Space Station (ISS). The ISS is a habitable artificial satellite where scientists can conduct experiments in a laboratory in space. The space station was built piece by piece. The first piece was sent November 20, 1998, and the station was completed in

15 years. In 2010, the ISS was given additional diplomatic, commercial, and academic roles.

Notable space probes include Luna 3, Luna 9, and Luna 16. Luna 3 was the first mission to get a picture of the far side of the moon. Luna 9 was the first man-made object to land on the moon. Luna 16 is the first robotic probe to return a sample by reaching the moon and coming back. Many other space probes are important to astronomy.

Launched on September 5, 1977, the *Voyager 1* probe weighed 700 hundred kilograms. As of January 2019, *Voyager 1* was still operational, part of the longest-lasting NASA mission, having been in service more than 40 years. *Voyager 1* was the first probe to send detailed images of the moons of Jupiter and Saturn. Now the farthest human-made object from Earth, *Voyager 1* has sped away from the solar system at a higher speed than any other probe. As of January 2019, *Voyager 1* was over 21.5 billion kilometers from the sun. On August 25, 2012, *Voyager 1* became the first human-made object to leave the solar system and the influence of the sun and enter interstellar space. The plasma sensor on *Voyager 1* ceased to function in 1980, but NASA scientists were able to use a 2012 solar flare to measure vibrations of the plasma surrounding the craft, allowing them to determine that the plasma was much denser than it had been in the far layers of our heliosphere. From this, they concluded that the craft had broken beyond the heliopause.

The Cassini-Huygens space probe to Saturn launched in 1997 and entered Saturn's orbit in 2004. Later that year, the Huygens probe separated from Cassini and landed on Titan, one of Saturn's 53 moons. The Cassini probe has made innumerable discoveries, including the existence of large methane lakes on Titan and an ice-covered sea on Enceladus. In September 2017, the probe crashed into the surface of Saturn as its "grand finale."

Satellites and space probes are still being made today to advance our space travel and exploration. The number of satellites is limited because of waste in orbit; however, more deep space exploration probes are still planned actively today.

Scotchgard Fabric Protector. See Sherman, Patsy O'Connell

Sherman, Patsy O'Connell (1930–2008)

Patsy Sherman was a chemist who, along with colleague Sam Smith, invented Scotchgard Fabric Protector, a moisture and stain repellent, while employed at 3M Company in the 1950s. The discovery of the substance was largely by accident—when someone in the lab spilled a new latex material onto a shoe and Sherman discovered that it could not be washed off. She and her supervisor began to think of possible applications for such a waterproof material, and in 1955, Sherman and Smith introduced Scotchgard, a protective coating for fabrics and other materials.

Sherman began working for 3M immediately after college and remained there for 40 years, until her retirement in 1992. She rose through the ranks from research specialist to manager of the chemical resources division to head of technical development and held several patents for fluorochemical polymers and processes.

The Scotchgard product made 3M a household name and earned the company millions of dollars, but in 2002, it was announced that 3M would remove Scotchgard from the market over environmental concerns. The property that had made its chemical makeup attractive as a fabric protector, its insolubility or inability to be broken down, also made it potentially dangerous. Although tests of potential toxicity to humans and to the water supply remain inconclusive, elevated levels of perfluorochemicals have been found in the blood of company employees as well as in certain animal species. In light of this research, 3M chose to exercise

what it called “responsible environmental management” in phasing out the current chemical process used to create Scotchgard products. The product is still available as the company experiments with alternative formulas, and government organizations will continue to monitor the potential environmental and health effects of perfluorochemicals.

Sherman was committed to science education and was often an invited speaker to serve as a role model for young students. She received the Joseph M. Biedenbach Distinguished Service Award of the American Society for Engineering Education in 1991. In 2001, she was inducted into the National Inventors Hall of Fame, one of only a handful of women to be so acknowledged, and in 2002, she was one of 37 inventors who appeared at a celebration of the 200th anniversary of the U.S. Patent and Trademark Office. She was a longtime member of the American Chemical Society.

Shippingport Atomic Power Station

The Shippingport Atomic Power Station in western Pennsylvania was the first full-scale nuclear electric power plant meant exclusively for peacetime uses. Its location was the Beaver Valley, about 25 miles from downtown Pittsburgh. Pittsburgh’s Westinghouse Electric built the reactor. It was managed by Duquesne Light Company and went on the grid in August 1956. The power station was built in 32 months at a cost of \$72.5 million. It was an experimental reactor known as a “light water thermal breeder” and was distinguished by its ability to transmute inexpensive thorium-232 to a fissile fuel, uranium-233. Shippingport had a modest capacity of 60,000 kilowatts. Its basic function was

creating heat from nuclear fuel fission to generate steam to turn turbines, thus generating electricity. It was the first result of President Dwight Eisenhower’s Atoms for Peace program. After 25 years of successful service, Shippingport became the first nuclear reactor to be successfully decommissioned (this was completed in 1985). Atoms for Peace was one of the successful government and business programs that founders Alexander Hamilton and Henry Clay had envisioned, and it ranks with the Erie Canal, National Road, the Hoover Dam, and the 1960s U.S. space program.

The high cost involved in research and development and construction required an alliance of business and government. Duquesne Light teamed up with the new Atomic Energy Commission of the Eisenhower administration and committed \$30 million to the project over five years. Duquesne Light’s commitment came from its use of coal in the already smog-filled skies of the steel city of Pittsburgh, which often had the sun blotted out by smog in the afternoon. Smog and soot had plagued the area for over a century. Shippingport was a blend of efforts by the navy’s Admiral Hyman Rickover, Duquesne Light Company, Westinghouse Electric, and the Bettis Atomic Power Laboratory under the political leadership of President Eisenhower. Such a government-corporate alliance would take strong leadership, and that leadership is attributed to Admiral Rickover. The Atomic Energy Commission supplied 90 percent of the overall costs and assumed the legal liability for the project. Westinghouse Electric functioned as the general contractor for the construction. The project required government support, because fossil fuels were abundant at the time.

Admiral Rickover would leave a distinctive mark on America’s nuclear energy industry. He had been working with Westinghouse Electric since the early 1950s to develop nuclear submarines and aircraft carriers for the navy. Rickover had been behind the building of the Bettis Atomic Power Laboratory outside Pittsburgh in 1948. It was here that the Mark I submarine nuclear reactor was built at a cost of \$30 million. Rickover’s success made him the logical candidate to head up the Atomic Energy Commission in 1953. Rickover approached Shippingport as an example of

peaceful uses for atomic energy. He demanded reliability and safety throughout the design-and-construction phase. In addition, he required low-grade fuel versus enriched uranium in order to prevent diversion of nuclear fuel elements from use in nuclear weapons. The Shippingport plant was built specifically to advance the use of nuclear power, and it was to be a model for the future. Rickover's attention to the safety mission and his autocratic management style won over the public, allaying its concerns about nuclear energy. Rickover continued the development of nuclear submarines using the same technology. As construction started at Shippingport in 1954, the USS *Nautilus*, the nation's first nuclear submarine, was launched. The design of the nation's first nuclear aircraft carrier, the USS *Enterprise*, was started in 1954 as well, and it launched in 1960. The navy's outstanding safety record in nuclear propulsion remains part of the Rickover legacy.

Positive publicity was a key goal of both Atoms for Peace and the construction of the Shippingport plant. On September 6, 1954, President Eisenhower waved a neutron wand in Denver, Colorado, to signal a bulldozer in Shippingport to start construction. Eisenhower's address was televised to workers and guests at the construction site. Shippingport functioned faultlessly up to 1964, when it was shut down to install a new core to expand the capacity to 100,000 kilowatts. In 1974, the plant was shut down for a mechanical problem in the turbine. The Department of Energy used the time to convert Shippingport to a light water breeder reactor. President Jimmy Carter dedicated the new reactor in 1977. Carter was a nuclear engineer and a graduate of the navy's nuclear submarine program. The plant was decommissioned in 1982 after 25 years of very successful operation. General Electric was hired to be the general contractor to do the shutdown, deconstruction, and cleanup. Final deconstruction was completed in 1985 at a total cost of \$98 million. The site was graded, seeded for grass, and turned over for unrestricted use.

Shippingport proved the economic feasibility of breeder technology. The breeder reactor concept was based on the scientific principle that a reactor using low-grade fuel could produce more nuclear fuel than it consumed. However, the cheap availability of enriched

uranium allowed more conventional reactors to dominate the future market for nuclear power plants. The safety record of the plant was near perfect, thanks to redundant containment design, which assured no escape of radiation to the environment. The design used low-pressure steam created in a secondary exchange of heat, which isolated this secondary water from the radioactive inner system. In general, nuclear power gained wide acceptance thanks to Shippingport, until the Three Mile Island accident in 1979 (ironically a mere 80 miles east of the Pittsburgh area).

Silent Spring (1962)

Rachel Carson's (1907–1964) book, *Silent Spring*, calls attention to the dangers of the widespread overuse of synthetic chemical pesticides. The book was translated into several languages and was a worldwide best seller. Two important documentaries on the book were broadcast on television (CBS, 1963 and PBS, 1993). The book has been credited with the rise of the environmentalist movement of the 1970s. Unfortunately, Carson, already a national literary celebrity before she wrote the book, did not witness the full extent of her influence, because she died from breast cancer two years after its publication.

In the book, Carson argues that human tampering with nature can have disastrous results. Carson explains the multifaceted problem in a clear and moving text, suggests some natural alternative pesticides, and challenges the government and society to make necessary changes. She also argues that scientists'

desire to control nature is founded on an arrogant belief in the superiority of science and technology. She argues that all living things on the earth, from the tiniest microbes to the largest mammals, are part of the same fabric of nature. If one part of the fabric is abused, the negative effects are felt by the rest of the plants, animals, and humans. For example, when synthetic toxins are applied to insects, all the life-forms that are higher on the food chain ultimately ingest the same poison.

Carson formed the idea for an article on the possible harmful side effects of the use of synthetic chemical pesticides after a friend informed her that birds were dying in her hometown after local authorities sprayed dichlorodiphenyltrichloroethane (DDT) to control mosquitoes.

Before World War II (1939–1945), exterminators often used arsenic-type pesticides to get rid of unwanted insects. Although these types of poisons had harmful side effects, they paled in comparison with the strength of the pesticides that were developed and deployed after the war. This phenomenon occurred due to two main reasons. First, the high degree of specialization in research and development led to the fragmentation of scientific knowledge. For example, a scientist developing an effective pesticide to control a certain insect population was unlikely to consider the pesticide's harmful effects on birds or fish. Second, perhaps due to the legacy of the war, pesticide manufacturers tended to think in terms of waging “total war” on an enemy. Therefore, they developed synthetic toxins (much more powerful than natural toxins) with the ability to saturate and devastate target areas over an extended period of time. The feature of extended saturation, according to Carson, is instrumental in causing all sorts of health problems, including cancer.

Carson relied on her undergraduate and some graduate background in zoology and her gift for clear but poetic expression to create a compelling case. In spite of Carson's standing as a writer, she had difficulty finding a willing publisher. After some time, Houghton Mifflin (a book publisher) was her only outlet. Consequently, she expanded her article into a book with more than 200 pages. Critics questioned Carson's credentials and labeled her an emotional alarmist. They argued that synthetic pesticides were safe and

that no scientific proof existed of a definite link between pesticides and cancer.

Carson did not call for an end to the use of all pesticides. She acknowledged that pest control was necessary for agricultural production. She also accepted the realities of free enterprise, in which businesses often value quick profits over concern for possible long-term environmental issues. Carson called for a more controlled use of pesticides, and she made specific recommendations for the use of certain more environmentally safe natural pesticides. She held politicians, more than any other group, responsible for the state of affairs, because she believed that they were put in office to serve the public good. Government agencies responded to Carson's challenge with the creation of regulation agencies. Although very few pesticide-related laws were passed, the book created a lasting awareness in government and in society of the need to balance technological innovation with public safety.

Silicon Valley

Northern California's Silicon Valley is the world's major hub for technology companies. Silicon Valley holds the headquarters for some of the world's largest companies, such as Netflix, Google, Tesla Motors, and Silicon Graphics, just to name a few. The estimated net worth of Silicon Valley is estimated to be around \$2.8 trillion. Silicon Valley has paved the road for innovation with new ideas and concepts, using technology to elevate services, products, and business to new heights.

The fabled Silicon Valley rests in the southern region of the San Francisco Bay Area. It lies in the

Northern California's Silicon Valley serves as the global center of electronic technology. Corporate giants like Adobe, Apple, and Google have headquarters there. (Ken Wolter/Dreamstime.com)

Santa Clara Valley within the county of Santa Clara, California. At the end of the 1800s, it was a key location for telegraph and radio companies, and so it was already part of the history of technology before it earned its name. It was the first location the United States to do a ship-to-shore wireless message by telegraph because of its optimal ports. This act of long-distance communication helped springboard wireless communication to the world. In 1909, it became the area with the first-known radio station in the country, which was in San Jose, California: KQW.

In 1933, the U.S. Navy purchased Moffett Field, which led to the government's huge investment in the area for technology and testing for military purposes. Moffett Field has been a major location for the study of aerospace engineering and flight. Ames Research Center was established in 1939, and new jobs encouraged people to move into the vicinity. The most notable employer was Hewlett-Packard (HP), founded by William Hewlett and Dave Packard. HP made radar

and artillery technology during World War II, and it has been an important technology company since.

William Shockley, John Bardeen, and Walter Brattain created the transistor at Bell Labs in 1947. In 1954, Shockley left Bell Labs and created his own transistor company in Silicon Valley, using silicon as a key component in his work. This would help give Silicon Valley its name. Shockley Semiconductor Labs revolutionized the creation of transistors by using silicon instead of germanium. It hired people from Stanford University, experimenting and revolutionizing the electronics industry. When eight of Shockley's employees quit to create their own company, they were dubbed the "Traitorous Eight"; they were Victor Grinich, Julius Blank, Eugene Kleiner, Jean Hoerni, Jay Last, Gordon Moore, Sheldon Roberts, and Robert Noyce.

The Traitorous Eight partnered with Sherman Fairchild and created a new company called Fairchild Semiconductors. They built hardware for the Apollo

space program, which further cemented the importance of these technologies. Eventually, some of the Traitorous Eight left and created their own companies. Xerox opened and created the PARC Lab in 1970, which created technologies such as Ethernet computing and an early graphical user interface. Dan Hoefler wrote an article called “Silicon Valley U.S.A.,” and the nickname stuck.

With the creation of the personal computer and the Internet, other companies flooded the computing field, including Atari, a company that created video games. Apple also moved to Silicon Valley, and by 1980, it was already showing signs of being a hub of computing technology. Companies like Google and PayPal were making waves around the world from humble beginnings. Growth has not slowed, with Tesla Motors and Uber appearing, just to name a few.

Silicon Valley always will be linked with the improvement of humanity with technology. Starting with its humble beginnings in radio, its wide range of companies today tackle all aspects of life and business as technology continues to improve. Silicon Valley is the home and very face of technology. It is where technological ideas thrive and change never stops.

Single-Chip Microprocessor

A single-chip microprocessor is a central part in most computerized devices today, such as personal computers and smartphones. It is a processor for a computer that allows the functions of a computer's central processing unit, also known as a CPU, to take place on a single integrated circuit or a few integrated circuits. A

microprocessor is not limited to a single use; rather, it is multipurpose, processing data that is instructed to be stored in memory and then displayed. Microprocessors contain both combination logic and sequential digital logic. Microprocessors operate based on numbers and symbols represented with the binary system.

The term “microprocessor” was first used to describe a custom integrated circuit that Viatron Computer Systems used in what was known as “System 21,” a small computer system announced in 1968. By the late 1960s, many computer designers, including IBM, the biggest competitor in technology at the time, aimed to integrate computer processing unit (CPU) functions onto MOS LSI chips (MPUs).

Intel, in 1968, introduced the first commercial four-bit microprocessor, known as the Intel 4004. Bits, a measure of the power of a microprocessor, allow processors to function. The more bits, the more effective the processor. The four-bit chip gave some weight to the prediction known as Moore's Law: that the capacity of integrated circuits doubles every two years.

Intel released the first 8-bit microprocessor, the 8008, in 1972. Many other companies had become interested in developing microprocessors, but by the mid-1970s, Intel introduced the 8080, an eight-bit microprocessor that had a huge impact. By the mid-to-late 1970s, 16-bit and 32-bit microprocessors appeared. But 16-bit microprocessors were short-lived, as they were slow though more technically advanced. National Semiconductor entered the field with the PACE microprocessor, but it was also slow. By the 1980s, 32-bit microprocessors began to hit the market, introduced by National Semiconductor and Hewlett-Packard. These are seen as the forerunners of modern microprocessors.

By 1992, 64-bit microprocessors were available and became mainstream in personal computers. Intel and AMD had by then dominated the battle of microprocessor advancements. Finally, RISC microprocessors from the mid-1980s to early 1990s were initially used for special machines, but they gained wide acceptance. RISC chips were intended to be the dominant chip by limiting more complex instructions and relying more on simpler ones, allowing for quick responses. RISC chips are still used today, although they are not as common as 64-bit chips.

One of the earliest uses for microprocessors was in electrical calculators. Today, they are used in many devices such as cell phones, personal computers, and cars. The single-chip microprocessor has advanced over the past century, yet the development of this technology is not over; nor has it likely even peaked. Microprocessors will open the door for many more creations, and should permit even more transistors to be placed within them. Moore's Law of doubling capacity every two years stood the test of time for a while, but now it is unclear whether it can withstand the challenges of further advancements.

Skylab

Skylab was a U.S. space station that three crews occupied between May 1973 and February 1974 and conducted countless experiments and observations on. After several years, the space station fell back to earth. Perhaps Skylab's greatest achievement was fostering support for the space program as the public became fascinated with space technology and innovation.

Six years before the manned Apollo spacecraft landed on the moon in 1969, the National Aeronautics and Space Administration (NASA) began the Apollo Applications Program (AAP). Skylab was the size of a small house and weighed about 100 tons (on earth). It had four separate units. The Orbital Workshop (OWS),

the main unit, was a cylinder 14 feet long and 22 feet wide, with a volume of 9,550 square feet. OWS housed food lockers, refrigerators, water tanks, space suit lockers, crew quarters, and an experiment station. Another smaller unit (AW) contained the station's control and monitoring center and access for crew members to conduct space walks. Skylab also contained the Apollo telescope mount (ATM), a powerful telescope not hampered by Earth's clouds or atmosphere. The space station contained a multiple docking adapter (MDA), which was used to dock with Apollo spacecraft that transported crew members from and to Earth.

Besides the four units, the space station contained tons of scientific equipment. For example, it contained various types of cameras such as spectrometers (instruments that measured wavelengths of light) and ultraviolet telescopes (instruments that measured the portion of the electromagnetic spectrum with shorter wavelengths than visible light). The total length of the space station and an attached Apollo spacecraft was 120 feet. AAP's plan was to reuse hardware from the Apollo program to build Skylab. After the Apollo 20 mission was canceled, for example, engineers repurposed a Saturn V rocket into the station's OWS unit.

The unmanned Skylab 1 mission was successful in getting the space station into orbit on May 14, 1973. However, Skylab was damaged during liftoff when a protective shield came loose and smashed against the station's two main solar panels. One panel was completely destroyed, and the other was badly damaged. Consequently, Skylab 2, the mission to get a crew on board the station, was postponed for several days as engineers and the crew devised ways to fix the damage. Without the protective shield, parts of the station were uninhabitable due to high temperatures up to 135°F.

In addition, the station's energy levels were drained to one-third capacity due to the inoperability of the two main solar panels. As soon as the Skylab 2 crew arrived on Skylab, it conducted space walks to repair the damage on the exterior of the space station. It deployed a gold parasol-type sunshade to replace the missing shield, which cooled the station enough to allow the crew to work inside. After days of trying, on day 14, the crew fixed one of the main solar panels. Full power was restored, and the crew spent many

hours conducting planned space-environment-type experiments.

The Skylab 2 crew spent 28 days in space. When it returned to Earth, doctors found that weightlessness had caused dramatic negative effects on its members' health. The crew lost about 10 percent of their body weight, 10 percent of their red blood cells, 30 percent of their arm strength, and 60 percent of their leg strength. However, the health of the two next crews fared much better as a result of the implementation of a more intense exercise routine. In fact, later crews installed a makeshift treadmill. After securing themselves, crew members would slide-walk on a Teflon sheet while wearing socks. The Skylab 3 crew lasted 59 days in orbit, and the Skylab 4 crew lasted 84 days. All crews experienced motion sickness, but they all adjusted to the weightlessness after a few days.

All three crews conducted experiments and made observations in space. They explored the effects of weightlessness on the central nervous system, cells, embryos, fluids, magnetics, crystal growth, and particle physics. Some of their experiments had been requested by American students. For example, a high school student wondered if spiders would be able to spin their webs in space. Two spiders were transported to Skylab. At first, the spiders had a difficult time making their webs, but they adjusted after a few days. The crews also observed celestial objects in space including the earth (99 passes), the sun (941 man-hours), and the comet Kohoutek (which had been discovered in March 1973).

Although the project experienced difficulties, many scientists assessed that the Skylab missions had been a success. In total, all three crews conducted almost 300 experiments and spent 171 days in space, which was longer than all previous American manned space missions combined. Skylab fostered the public fascination with space technology and increased support of the space program in general. Another important result was that Skylab showed that weightlessness was not an absolute prohibitive barrier for human space exploration. After the Skylab 4 crew returned to Earth in early 1974, the space station was left unmanned for several years.

Engineers had not equipped the station with an independent reboost mechanism. Consequently, when the space station began to slowly lose orbit, a rescue

mission was planned. However, the station fell to earth (July 11, 1979) before a crew could save it. Skylab burned up and broke into many pieces as it reentered Earth's atmosphere. Debris was scattered over the Pacific Ocean, Indian Ocean, and a sparsely populated region of western Australia. No major damage was caused. The end of Skylab simultaneously signaled the end of the Apollo era and the beginning of the Space Shuttle and International Space Station eras.

Skywalker Ranch

George Lucas's Skywalker Ranch is a private movie-making retreat and the home of Skywalker Sound and the George Lucas Educational Foundation. George Lucas bought land in 1978, intending his ranch there to be a place of film-making collaboration.

Skywalker Ranch is located in Marin County, California. George Lucas bought Skywalker Ranch for \$100 million; it consists of 4,700 acres with 14 buildings, animals, vineyards, a restaurant, a hilltop observatory, a theater, a hotel, soundstages, postproduction studios, and the Lucasfilm Research Library. Sprocket Systems, the company that produced the sounds in *Star Wars*, moved to Skywalker Ranch in 1987 and change its name to Skywalker Sound. Skywalker Sound has over 500 employees and fills 150,000 square feet of space. The theater called the Stag has an advanced sound system, multiple screening rooms, and underground parking.

Many top film directors have worked at Skywalker Ranch. Clint Eastwood used Skywalker Sound to produce his audio for *Million Dollar Baby*. Sean Penn

and Paul Thomas Anderson worked on their films *There Will Be Blood* and *Into the Wild* there. Tom Hanks also used Skywalker Ranch as a resource for his famous film *Cast Away*, which was nominated for two Oscars. Skywalker Sound has worked on other famous films such as *Star Wars: The Force Awakens* and *Jurassic World*. Skywalker Sound works on about 40 movies a year. Skywalker Sound is the main reason that people visit Skywalker Ranch.

Many residents around Skywalker Ranch claim that it creates light and noise pollution. Lucas submitted plans to build a studio on the property over 25 years ago, but area residents have blocked his efforts to complete the project. Lucas was also blocked in his efforts to build affordable housing for the teachers and police personnel who could not afford to live in Marin County. Marin County planners and elite-class residents have enthusiastically blocked these plans.

George Lucas wanted to create his own library to help Lucasfilm productions. In 1978, the Lucasfilm Research Library was established in Los Angeles offices. In 1985, Lucasfilm Research Library was moved to the main house at Skywalker Ranch. It has been said that to enter the library is to enter the brain of George Lucas. George Lucas's art collection also resides at Skywalker Ranch.

In 2007, Lucas was given permission to build two more screening rooms in his theater. In 2015, he intended to provide 225 units of affordable housing at the ranch. Ultimately, he would like the ranch to become a film school.

Smallpox, Eradication of

Smallpox was a deadly viral disease that decimated populations and wiped out armies. Caused by the variola virus, it was probably originally carried by rodents

and made a jump to humans. Where this first occurred is unknown, but it likely began in an area such as Egypt's Nile and/or India's Ganges River valleys, which were densely populated enough for the virus to pass from person to person. Symptoms include a high fever and a rash that turns into sores that break open and release more virus. The sores scab over and heal, often leaving severe scars. About 30 percent of smallpox victims die.

As early as the 10th century, it was noted that people who survived smallpox never caught it again. From there, the practice of variolation began. Named after the virus itself, variolation involved making a scratch in the skin of a healthy person and introducing material from a sore from a patient with active smallpox, which caused a less severe form of the illness. This procedure did carry some risk; variolated people could still spread the disease, and some died.

In the United States in 1716, famed Puritan minister Cotton Mather (1663–1728) wrote to the Royal Society of London about a method of inoculation that seemed to cure smallpox. He had learned it from an enslaved member of his household, Onesimus, who had described undergoing a similar inoculation in his childhood in Africa and claimed that being injected with a small form of the virus had prevented him from developing smallpox despite exposure to many other victims. In 1721, Mather used the process himself to help fight one of Boston's many epidemics. In 1736, Benjamin Franklin, devastated by the loss of his son to the disease, suggested and likely funded the creation of a pamphlet explaining inoculation to parents. Some 2,000 pamphlets were distributed.

In 1738, some 800 people in Charleston, South Carolina, were inoculated, and when smallpox hit, only eight deaths were reported. When this story reached London in 1743, it led to the practice being revitalized there.

In 1945, the United States joined 26 other allies from World War II in creating the United Nations to foster cooperation among countries. One of its outgrowths was the World Health Organization, which was established in 1948. At WHO's annual World Health Assembly in 1958, Viktor Zhdanov, the Union of Soviet Socialist Republic's (USSR) deputy minister for health, made a proposal for a program to eradicate

smallpox. At that time, smallpox had already been eliminated in the USSR, North America, and Europe, and he saw global elimination of the illness as a very real possibility. He argued that funding an eradication program would save money in the long term, as countries that were already free of the illness were forced to spend large sums on vaccination and revaccination of its citizens. His proposal was accepted in 1959.

The initial program was small, with two staff people and less than \$100,000 in cash and donations. The dearth of funding made progress slow until 1966, when WHO adopted the Intensified Smallpox Eradication Programme, partly as a result of a funding pledge from the United States. The new program came with greater resources, including an initial budget allocation of \$2.4 million, and a goal of eliminating smallpox by 1976.

The public was made aware of efforts via print publications, television documentaries, news stories, and even commemorative stamps issued by a number of countries. WHO worked with laboratories to assure adequate stocks of vaccine. Between 1967 and 1979, 360 million doses were distributed to 70 countries and organizations.

Another vital piece was surveillance and data collection—ensuring that suspected cases of smallpox were promptly reported and investigated, and using the number of new cases as a measure of program efficacy. From there, it could be determined for each country what steps should be taken to keep the number of cases going down. Any smallpox patients found were quarantined (usually at home) to prevent further spread.

The last naturally occurring case was in a hospital cook in Somalia in October 1977. WHO officially declared smallpox eradicated on May 8, 1980.

Smoke Detector

A smoke detector is a device that is designed to alert homeowners and businesses to the presence of fire by detecting smoke. In 1965, Dewey Pearsall invented the first affordable, battery-powered smoke detector for home use.

Prior to Pearsall's invention, smoke detectors were bulky, expensive, and unreliable. In 1890, Francis Upton patented the first automatic fire alarm, and in 1902, Englishman George Darby invented the first smoke detector.

Pearsall graduated from the University of Denver in 1947, and after serving in the Naval Air Reserve for six years, he went to work at Honeywell, a heating and air-conditioning company. In 1955, he left Honeywell to found Pearsall Company and then eight years later, Statitrol Corporation. It was at Statitrol that Pearsall realized that a mechanism designed to measure ion airflow could also be used to detect smoke. Pearsall designed a small home smoke detector that could be powered by a battery. He patented his design in 1973, and his company began to produce the "SmokeGard 700" two years later. Pearsall also worked with the National Fire Protection Association to change building codes to require smoke detectors. Pearsall sold his device to Emerson Electric in 1980.

Today, smoke detectors are found in the vast majority of American homes. The National Fire Protection Association believes that smoke detectors reduce fire-related injuries and deaths, but only if the smoke detectors are installed correctly and tested regularly.

Primary Document: Chris P. Borreson's Account of the Iroquois Theater Fire (1904)

This recounting of the famous Iroquois Theater Fire by Chris P. Borreson, one of the few survivors, expresses the difficulty that people had in escaping the theater due to poor fire preparation and lack of fire safety regulations when the theater was constructed. This fire is one of the most important in the history of U.S. fire safety because the incident led to the development of comprehensive fire laws, maximum occupancy requirements, and many other aspects of modern fire safety. Borreson's recollection emphasizes the damage that this fire caused and the problems that people had escaping a large building without any clear exits.

Chicago, Jan 12, 1904—Dear Brother and Parents: I am all right. I was in the theatre at the time of the fire with some of my friends, but I managed to get out alive. I was badly hurt on the arm and leg. I just got out of the hospital today and could not answer your letters any sooner. The fire was the worst thing I ever

saw or was ever in. All the boys had their girls along. I had a time to get the young lady and her sister, who were with me, out. But we did get out, but we had a job of it. Everybody went away and the smoke and fire were terrible. I was behind the girls and when we got to the door, pushed them out and then we all went down the stairs. That is the way I got my arm and leg hurt. I don't know how I got out after that. The next morning I found myself in the hospital. I will not be able to do any work for a month or so. I do not care to get in a place like that again. I will be all right in a few weeks. Tell mother that I am O.K. I lost my hat and one shoe in the fire and my coat was torn all to pieces and I got a bad knock on the head that put me to sleep. I hope you are all well. Best regards to all, your brother, Chris Borreson Chicago, Ill.

Space Science and Technology

The interest in what may lay outside of the earth's grasp has always been an enticing subject. Isaac Newton and Galileo Galilei theorized about what might be outside of the earth's atmosphere. In the early 1680s, Newton developed the idea of gravity as well as his laws of physics. Galileo Galilei is considered the inventor of the optical telescope. In the United States, the National Aeronautics and Space Administration (NASA), founded in 1958 by President Dwight D. Eisenhower, focuses on space science and technology.

Since the inception of NASA, the United States has made great progress in expanding the boundaries of what we know about space. Keith Glennan was an early NASA administrator; a letter to him from President Eisenhower mentions meteorological satellites that it sent up in its first three years—such as Trios I

and Trios II, which promised to revolutionize meteorology and global communication.

NASA has moved from such satellites to sending unmanned spacecraft to such celestial bodies as Comet 67P/C-G, the asteroid 25143 Itokawa, the moon, Venus, Mars, and Titan (Saturn's largest moon). NASA also landed a manned spacecraft on the moon in July 1969 and sent unmanned spacecraft to circle around the dwarf planet Pluto.

The Mars rover *Curiosity* functions 225 million kilometers away from earth and is self-sufficient without maintenance. It can trek up to 100 meters (328 feet) every Martian day. The Mars Rover transmits data at about 12,000 bits per second, but it can do this directly to Earth only between 90 minutes to five hours per day due to power limits and thermal conditions. The Rover is currently searching for early signs of life because of the evidence of water on Mars.

Space science and technology is a rapidly expanding field. From the speculations of Isaac Newton and the observations of Galileo Galilei, NASA is taking further steps in discovery, laying a foundation for future scientists to build upon.

Primary Document: Account of Astronaut David Alexander Wolf Voting in Space (1997)

Astronaut David Alexander Wolf is on the record for taking four flights into space, seven spacewalks, and spending 128 days on the Mir Space Station. Before becoming an astronaut, Wolf earned degrees in both medicine and electrical engineering. He is also remembered for being the first American astronaut to vote while in space, which he did in 1997.

Vote While You Float: An Astronaut Voting Story

With the excitement of getting to the polls on Election Day many people will have a hard time keeping their feet on the ground, but astronauts who vote literally have to strap themselves down so they don't float away.

Astronauts orbit the Earth at 17,000 miles per hour, but thanks to a bill passed by Texas legislatures in 1997 that put in place technical voting procedure for astronauts—nearly all of whom live in Texas—they also have the ability to vote from space!

For astronauts, the voting process starts a year before launch, when astronauts are able to select

which elections (local/state/federal) that they want to participate in while in space. Then, six months before the election, astronauts are provided with a standard form: the “Voter Registration and Absentee Ballot Request—Federal Post Card Application.”

“Space voting” was first used the same year it was implemented in 1997. NASA astronaut David Wolf became the first American to vote in space while on the Russian Mir Space Station. Current space station resident astronaut Shane Kimbrough is the most recent astronaut to take advantage of the opportunity.

While astronauts don't have to wait in line for his ballot like the rest of us, there is one disadvantage to voting in space: they miss out on the highly coveted “I Voted” sticker.

Stealth Technologies

“Stealth technologies” include a range of tactics for undiscovered or undetectable travel. Though the term “stealth” is more often applied to air travel, stealth technology can be used on the ground as well. The ability to gather data without detection has been crucial to the post–World War II American military. The initial use of stealth technology applied to airplanes,

because the thin material that covers them is perfect for reflecting waves produced by radar. This discovery changed the game, considering the range of tactical abilities that planes possessed during World War II; jets served as a primary weapon. The ability to detect enemy aircraft as well as prevent detection of one's own planes became a priority. Once the use of radar to track aircraft materials became commonplace, methods for cloaking aerial machinery gained importance.

Northrop Grumman's B-2 Spirit, better known as the Stealth Bomber, was under development in the 1970s and 1980s. Though now a successful airplane design, the B-2 program's billion-dollar price tag made it controversial. (U.S. Department of Defense Visual Information Center)

Methods for decreasing an airplane's level of observability include shaping the plane in a way that radar waves reflected from it are angled away from radar equipment, and also covering the airplane in materials that absorb radar signals. These techniques meant that stealth planes did not have a rounded, aerodynamic shape but one composed of sharp angles, bringing the level of detection down from that of a plane to that of a bird. The only exception is when the aircraft banks or lands. These create a perfect ray of radar reflection straight to the detector.

The first undetectable aircraft in the United States was created by accident. The YB-49 Flying Wing was tested until 1948, when it crashed in the Mojave Desert. The plane went unnoticed by the then-current level of

radar detection, leaving observers shocked when it suddenly appeared overhead. The YB-49 never went into production, and it was eventually replaced by the Convair B-36, which did not have stealth technology.

Stealth technologies were first proposed as a tactic in 1953 for flying out of range of Soviet fighters, missiles, and radar. U.S. Air Force officer John Seaberg invited Bell Aircraft, Martin Aircraft, and Fairchild Engine and Airplane to submit ideas for accomplishing this task. When the Lockheed Aircraft Corporation heard of the competition, it began development despite the lack of request for it to do so. Lockheed's Clarence Kelly Johnson was asked to design the craft and incorporate executive John Carter's suggestions to eliminate landing gear and other unnecessary loads. Johnson

was an aeronautical engineer for Skunk Works, a division of Lockheed. His work on the Lockheed XF-104, an experimental jet with undetectable aerial technology, won the Collier Trophy in 1958.

The discovery that the size of a plane was not the only element that played into the amount of radar it reflected resulted in the Quail decoy drone. In 1961, it produced the same radar frequency as a much larger plane, which led to one of the first stealth technologies—simply flying planes higher to avoid radar detection. The techniques applied were dubbed “stealth” or “low observation” technology, but this eventually branched into “quantum stealth,” which worked on the basis of reflecting light rather than radar.

A short-term solution known as the U-2, or “Iron-Ball,” was developed at Lockheed in the 1960s. It was the first aircraft with radar-absorbing paint that successfully infiltrated Soviet territory until stronger radar detectors were developed. These more advanced radar detectors resulted in the U-2, piloted by Gary Powers, a spy doing reconnaissance over enemy lands, being shot down in 1962 with a barrage of missiles.

Even while Powers’s plane was crashing, another plane that could fly higher and faster was being developed with the idea of low observability. The A-12 would soon become the SR-71, able to reach speeds of Mach 3.3, or 2,215 miles per hour. This plane’s design was long and slim, with engines embedded in the wings and radar-absorbing material expanding past the paint surface. The political fallout from the Gary Powers event made it so that no more manned vessels were flown over Soviet territory. Instead, the A-12 was used to develop drones called D-21s that resembled the engine and wing of an A-12. These new developments collected data from over Soviet territory. The D-21 was launched from an A-12 with a high-resolution photographic camera and followed a predetermined course to provide information for ground troops. After four unsuccessful operational flights over the People’s Republic of China, however, the program was canceled in 1971.

In 1983, Lockheed Martin pioneered modern stealth aircraft by making planes faster, which gave radar detectors less time to pick up reflected frequencies. However, the faster a plane, the larger it had to become, meaning more surface area for radar to

bounce off of and negating any benefits that a speed increase might offer. The Tacit Blue Program was developed, declaring that with the proper stealth techniques, the ground game on the battlefield could be observed and reported on without detection—or fatalities.

Stealth technology has branched past working in the air to infiltrating troops on the ground. With quantum suits and parachutes, which bend and refract light, even fighters jumping from a plane or directly landing on the ground cannot be detected. When covering a human body, light-bending material only allows for sensors or human eyes to detect approximately 5 percent of a person’s shadow, leaving him or her 95 percent similar to the surroundings. Possibilities for this technology range from hiding the periscope of a submarine, invading an enemy camp without detection, assisting a sniper without cover, covering tanks so that they are not detected, and creating uniforms for troops to become invisible assailants.

Superconductivity

The ability of some materials to exhibit zero electrical resistivity and magnetic flux expulsion is termed “superconductivity,” and those that display it are referred to as “superconductors.” Three American researchers best modeled the theory of superconductivity: John Bardeen, Leon Neil Cooper, and John Robert Schrieffer. They described the phenomenon in

terms of electron pairing, and theirs was the first microscopic theory of superconductivity. In 1972, the three men were awarded the Nobel Prize in Physics for their theory, more commonly referred to as the “BCS theory” according to their initials.

The definition of materials as superconductors is distinguished by two properties. One is that they offer no resistance to the passage of electrical current. The disappearance of electrical resistivity allows a current to circulate inside the material without wasting any energy. The other property of a superconductor is its impermeability to magnetic fields. Instead of penetrating it, a magnetic flux field remains at its surface. The latter characteristic is known as the “Meissner effect.” Materials actually transition into a superconducting state—and so suddenly that they look like they are going through a phase change.

The research into this state peaked with the discovery of high-critical-temperature superconductors. They differ from conventional superconductors, whose electrical resistance drops to zero when they are cooled below a critical temperature. Exposing a superconductor to any magnetic field automatically decreases its critical temperature, but the greater the strength of the magnetic field present, the colder the material needs to be to transition. If the strength of the magnetic field goes above a critical level, the material will fail to superconduct. Simply put, superconducting materials lose their ability to superconduct regardless of how cold they are if subject to powerful-enough magnetic fields.

This discovery led to the distinction of type I and type II superconductors. Type I has only one critical field and is completely expelled from the magnetic field. Type II has two critical fields that make it semi-permeable to the magnetic field. There are 30 pure metals that display zero electrical resistivity at low temperatures and can block magnetic fields. The BCS theory articulates what constitutes a conventional superconductor and the properties that contrast the two types of superconductors. The theory states that electrons get together in what it calls “Cooper pairs” within a superconductor instead of traveling independently. This is thought to be due to their frictionless flow. Transition temperatures for traditional superconductors are in the absolute zero range, but now, we can

also synthesize “high-temperature” superconductors that transition at warmer temperatures.

Superconductors have become incredibly lucrative due to their enormous variety of applications. One application where superconductors perform life-saving tasks is in biomagnetism. Doctors use it to observe what occurs inside the human body. By applying a strong superconductor magnetic field to the body, hydrogen atoms in the body’s water and fat molecules absorb the magnetic field’s energy, which then exits at a frequency that can be graphically translated by a computer. Superconductivity can also be used to make electricity generation more efficient so that innovations such as high-speed magnetic-levitation trains, ultra-high-speed computer chips, and high-capacity digital memory chips are possible. Electric generators produced with superconducting wire are more successful than basic generators composed of copper wire. These electric motors are practically infallible, and they are half the size of conventional generators. In the future, superconductors may be used in power plants that can significantly reduce the emission of carbon dioxide into the biosphere.

Taussig, Helen (1898–1986)

Dr. Helen Brooke Taussig gained international acclaim for codeveloping the first successful “blue baby” operation for babies whose congenital heart defects cause their skin to turn blue from lack of oxygen. A Johns Hopkins pediatrician for most of her life and a leader among women in American medicine, Taussig saved countless lives by devising a method to correct infants’ heart defects. In addition to founding the field of

pediatric heart surgery, Taussig also played a major role in sounding the alarm regarding the use of thalidomide, a drug used by expectant mothers that caused birth defects in their children.

Born in Cambridge, Massachusetts, in 1898, Taussig was the youngest of four children who had the good fortune to come into a family that valued education highly. Her father, Frank W. Taussig, was an economist and professor at Harvard University who advised President Woodrow Wilson. Her mother, Edith Guild, had attended Radcliffe College. The family frequently socialized with the president and his wife, Edith Wilson.

Possibly the most influential factor in Taussig's drive to become a doctor was her mother's death from tuberculosis when Taussig was 11 years old. Taussig would overcome great odds to achieve her goal. Not only was she born a sickly child, but she also suffered from dyslexia; she later credited her father for helping her overcome this reading impairment. She did, however, always struggle with reading. Physician Helen Taussig founded the field of pediatric cardiology. She also played an important role in outlawing thalidomide, a drug prescribed to pregnant women for morning sickness that caused severe fetal birth defects. Taussig had an additional challenge that she later managed to parlay into a brilliant diagnostic tool; because she had lost her hearing thanks to childhood whooping cough, she had to rely on lipreading and hearing aids throughout the entire course of her career. Interestingly, her hearing impairment, rather than being a detriment, was actually considered a factor that contributed greatly to her success, thanks to her ability to differentiate between healthy and unhealthy heartbeats by touch.

Despite her many physical impediments, Taussig was an extraordinary student at her mother's alma mater, Radcliffe, where she spent her first two years of undergraduate study. She also became an excellent tennis player before transferring to the University of California, Berkeley, from which she graduated Phi Beta Kappa with an applied baccalaureate degree in 1921. From there she went on to Harvard, whose policy at the time prevented her from entering its then all-male medical school, although she was allowed to study histology on a noncredit basis. Taussig then went to Boston University, ultimately earning her

medical degree from Johns Hopkins University's School of Medicine in 1927.

Taussig served the first year of her internship at Johns Hopkins in the cardiology department, then two years interning in pediatrics. In 1930, she was put in charge of a heart clinic, where she began her research into heart defects. She was one of the first to use a system called fluoroscopy, then a relatively new x-ray technique.

Taussig soon zeroed in on a congenital heart condition called anoxemia, or "blue baby" syndrome. She used fluoroscopy to demonstrate that the infants who were afflicted with the condition suffered from leaky septums (the membrane that divides the heart's various compartments) and undersized arteries leading from the heart to the lungs. By applying the fluoroscopy method to examine sick babies' hearts, Taussig discovered links between abnormal hearts and birth defects, making the connection that a key component of infant mortality was that the ductus arteriosus, a blood vessel, closed at an inappropriate time.

At the same time, a heart surgeon in Boston, Dr. Robert Gross, had already created a surgical method to close the offending blood vessel when it stayed open unnecessarily in other situations; he suggested to Taussig that it might be feasible to construct such a method to create the missing blood vessel for blue babies.

In 1941, Taussig, inspired by Gross's insight, suggested the idea of the ductus operation to two coworkers at Hopkins—Alfred Blalock, a surgeon, and Vivien Thomas, a surgical technician. Taussig and Blalock experimented on dogs to perfect the operation, finally performing the operation on a one-year-old girl in 1944; the child survived for nine months after the operation. In 1945, Taussig and Blalock issued a report to the *Journal of the American Medical Association*, and their operation was soon being used worldwide.

Of perhaps equal importance to her contribution to the field of heart surgery was the connection that Taussig made after a 1962 tour through Europe. She found that an antinausea drug called thalidomide that was given to expectant mothers corresponded to disfiguring birth defects involving malformation of the limbs (phocomelia). Upon her return to the United States, Taussig sounded the alarm. Officials took her warnings seriously, and doctors stopped prescribing the drug.

In 1945, Taussig was awarded the Lasker Award for her blue baby operation, and in 1959, she was awarded a full professorship at Johns Hopkins—one of the very first women in Johns Hopkins's history to earn that distinction. She was elected president of the American Heart Association in 1965. She was also a recipient of the highest award given by the Johns Hopkins University School of Medicine, one of the first women to receive this honor.

Taussig remained at the Johns Hopkins Hospital until her retirement in 1963, not surprisingly working in the Children's Heart Clinic.

On May 20, 1986, Taussig was in a car accident near her home in Kennett Square, Pennsylvania, and died an hour later at Chester County Hospital. She was 87 years old. In keeping with her lifelong dedication to humanity and science, she donated her body to Johns Hopkins. Taussig never married and had no children.

Telephone Switching, Computerized

Before Erna Hoover, telephone switching was done by hand. A call would be made to a call center, where a human operator would direct the call to the correct receiver by virtue of a series of interconnected wires on a board. There were hundreds of jacks along the board, and the operator would have to search for the right cable for the correct jack. There were several employees at each call center routing the calls, but they could only handle so many at a time. This caused backups in the system. There were four main jacks shown on all the operators' switchboards, each for the main lines that connected calls. Once one of these lines was in use, a second call to that line could not be connected, so it was dropped.

To determine if the line was already in use, an operator would gently tap a cable plug against the rim of the jack. If it created a clanking noise, the line was in use. But this was an unsatisfactory way to handle calls. There were often jams where people's phone calls could not go through because the operators were busy dealing with a bombardment of calls. These large numbers of phone calls and delays needed to be addressed.

Erna Hoover contributed to the information technology world by creating a phone-switching system for phone traffic. Hoover was the daughter of a schoolteacher and a dentist. She was born on June 19, 1926, in Irvington, New Jersey, and sadly, her younger brother passed at the age of five from polio. Hoover was encouraged to learn, and she showed interest in the sciences at a young age. She earned her bachelor's degree at Wellesley College and then a PhD in philosophy and foundations of mathematics from Yale University.

Hoover was hired at Bell Laboratories, where she developed and patented the first computerized switchboard. This was a huge leap for the computer science industry, being a transition from electrical technology to computerized technology and paving the way for modern technology such as smartphones. Hoover's computerized switchboard involves a complex circuit board that allows phone calls to flow through more efficiently. Before this invention, the electronic system could only handle about 200,000 calls an hour, and if the calls came in too quickly, the system crashed and the calls would fail. Her invention allowed a larger number of phone calls to come in without causing the electronic server to freeze.

The computerization of the telephone switching board was a reliable alternative. This breakthrough led to a promotion for Hoover—one of the first women to be promoted to technical department head at Bell Laboratories.

Hoover is not mentioned often, but her contributions to computer science were crucial to jump-start the evolution of the telephone industry from the switchboard to the cell phone. In 2008, she was inducted to the National Inventors Hall of Fame and also given the Wellesley College Alumni Achievement award.

Thomas, Valerie (1943–)

Scientist Valerie Thomas patented the illusion transmitter, which transmits three-dimensional illusions of an object, in 1980. The transmitter was pioneering in 3-D technology and is still used today.

Born and raised in the state of Maryland, Thomas was very much interested in science as a child. At the age of eight, she witnessed her father tinker with the parts inside the family television and became curious about electronics and their functions. She read *The Boys’ First Book of Radio and Electronics*, which was filled with activities and projects, but her father was reluctant to help her despite his own interest in the subject. She attended an all-girls school where she was not encouraged to pursue science or math, though she did manage to take a physics course. At Morgan State University, she majored in physics and went to work at NASA after her graduation.

From 1964 to 1970, Thomas worked at NASA as a data analyst on the systems supporting satellite operations. After six years, she was put in charge of the team that helped create the Landsat program, which developed the longest-running technology that takes satellite images of Earth for applications in agriculture, geology, and education. Thomas became a team leader for the Large Area Crop Inventory Experiment (LACIE) in 1974, where she used space technology to help with wheat harvesting on a global basis. LACIE was a collaboration between the U.S. Department of Agriculture, NASA, and the National Oceanic and Atmospheric Administration (NOAA).

In 1976, she visited a scientific exhibit where there was a display that featured an illusion of a lightbulb that appeared lit even when the bulb was removed from its socket. This astounded her and led her to research the phenomenon. She discovered that two concave mirrors created the illusion. Flat mirrors have images that appear to be inside or behind them while concave mirrors can make images appear to be in front of them. At this moment, Thomas was sure that this

method of using concave mirrors could assist in her projects at NASA.

Thomas developed the illusion transmitter and received a patent for her invention in 1980. It paved the way for the birth of the modern 3-D imaging that we now see in television. This technology has also assisted the medical field; surgeons use her technology to help create 3-D images of the body. Thomas continued to work for NASA, rising through the ranks and becoming the project manager of the Space Physics Analysis Network (SPAN) in 1985 and associate chief of the Space Science Data Operations Office from 1986 to 1990. In 1990, SPAN was at the forefront of development of computer networking that led to today’s Internet. Thomas also participated in projects involving Halley’s comet, ozone research, and the Voyager spacecraft.

Valerie Thomas prided herself on giving back to community. Throughout her career, she spoke to countless groups of students from elementary to university level, as well as adult groups. She also served as a mentor in summer programs for students at the Goddard Space Flight Center. She also worked with organizations such as the National Technical Association (NTA) and Women in Science and Engineering (WISE), where she encouraged women and students of color to pursue careers in technology.

Valerie Thomas received the Goddard Space Flight Center Award of Merit and many more awards from NASA, including the Equal Opportunity Medal. Thomas retired from NASA in 1995, and in retirement, she mentors young people through the Science, Mathematics Aerospace Research and Technology Association and the National Technical Association.

Touch-Tone Phones

After rotary-dialing phones, the touch-tone phone was created. Many people have claimed to be the inventors of the touch-tone phone, but the Bell System is widely given the credit for commercializing it. Rotary-dial phones used the pulse dial system, which is a direct-current local loop circuit that is interrupted according to a set coding system for each transmitted digit and signal. The touch-tone telephone uses dual-tone, multifrequency signaling (DTMF), which is a telecommunication signaling system that uses voice frequency bands over phone lines. The Bell System trademarked this under the name “Touch-Tone” in 1963.

In 1962, Bell System displayed the touch-tone telephones to the general public to test out at the Seattle World’s Fair. The president of the United States, John F. Kennedy, even partook in the fair by keying “1964” on a touch-tone phone located in the Oval Office. The touch-tone phone was now ready to be sold commercially. On November 18, 1962, the first one was available to locals in Greenburg and Pittsburgh, Pennsylvania.

Through the advancement of touch-tone telephones, Western Electric created its ideal model, named the Western Electric 1500. It had 10 buttons. It was soon replaced with the Western Electric 2500 model, which had 12 buttons, adding the asterisk (*) and the pound (#) keys. John Karlin developed the now familiar four rows of three keys layout, to encourage accurate dialing.

Even though touch-tone phones were commercialized, the rotary-dial phone was still more common at the time. The biggest customers for the new phone in the beginning were businesses. Around 1979, the touch-tone phone was growing steadily in popularity but was not available in all areas. In the 1980s, its number of customers continued to grow, and by the 1990s, rotary-dial phones were no longer in the majority.

Today, touch-tone phones and the dual-tone, multifrequency signal continue to be used in the telecommunications world, but the smartphone is now on its way to replacing the traditional touch-tone phone.

Trans-Alaska Pipeline

The Trans-Alaska Pipeline System, or TAPS for short, is a crude oil pipeline traveling across 800 miles of Alaskan terrain connecting the oil fields in Prudhoe Bay to the harbor in Valdez, Alaska. It is one of the largest pipeline systems in the world. The 1973 oil crisis, which caused significant increases in the price of oil, spurred the initiative to drill for the oil found in Prudhoe Bay in 1968.

Construction of the pipeline was successfully legally halted from 1970 to 1973 due to opposition from conservationists and Alaskan Native groups. Conservationists opposed the construction of a crude oil pipeline in Alaska because they viewed it as a threat to America’s last wilderness frontier. They also highly opposed the construction of the Dalton Highway, a road system that runs parallel to the pipeline and was built specifically to make the construction of the pipeline possible.

Conservationists opposed the construction of this highway because, although they viewed the pipeline as a threat to the wilderness, the pipeline was only designed to last 50 years before being dismantled, whereas the highway system would be permanent. The pipeline needed to be elevated due to environmental studies initiated by conservationists because of their concern about the effects on wildlife. In particular, they were extremely worried about caribou herds. They believed the effect would be similar to that on the American bison populations during the period of the Transcontinental Railroad.

After a series of environmental impact studies and reports, changes in the original design were required.

The most noticeable was the elevation of the pipeline—and even burying it when necessary—to allow wildlife to easily pass. Other changes included installing devices to scatter heat buildup around permafrost and bridges to allow the pipeline to cross rivers and streams without much disturbance.

Native groups fighting for the rights to their land eventually came to a settlement in October 1971, when President Richard Nixon signed the Alaska Native Claims Settlement Act. Under this act, Alaskan Natives surrendered their land and received \$962.5 million and 148.5 million acres of federal land. After all the opposition had been addressed and settled and the oil crisis of 1973 occurred, increasing support for the exploitation of Prudhoe Bay's oil reserves, construction finally began in March 1975.

The large project attracted thousands of men and women looking for employment, creating many “boom-towns” along the route of the pipeline. The work in this environment was cold, difficult, and required gruesome hours, which caused various issues. At least 32 workers are known to have died as a direct result of construction injuries alone. After years of work, the last weld was finished at Pump Station 3 near Atigun Pass on May 31, 1977. However, the first barrel of oil did not reach Valdez until well over the anticipated nine-day mark; it arrived at the harbor on July 28, 1977. This delay was due to mechanical issues that stalled production.

As time has passed, oil production in the area is declining, posing an issue for the future of the pipeline. Alyeska Pipeline Service Company, the private company that currently owns TAPS, plans on closing down all but four pumps as supplies continue to decrease. However, improvements to the pipeline that induce low-flow rates could extend the pipeline's life to as late as 2075. Under law, all traces of the pipeline are required to be removed from the land after oil

extraction is completed. Although plans are being continuously updated, there is currently no set date for this deconstruction.

The pipeline has delivered over 20 million barrels of oil to Valdez harbor. After oil was discovered on Alaska's North Slope in 1968, companies such as Humble Oil, British Petroleum (now BP PLC), and Atlantic Richfield Company had begun looking for an efficient way to transport these oil reserves to an ice-free port, leading to the construction of the pipeline. At a rate of four miles per hour, ensured by multiple pumping stations along the pipeline, a barrel of oil takes an average of nine days to complete the 800-mile journey to Prince William Sound.

Primary Document: Bill to Reform the Trans-Alaska Pipeline System Authorization Act (1989)

The Trans-Alaska Pipeline has been a controversial issue since its beginnings in the 1970s. It was begun in 1974 after high oil prices made it economically feasible to extract the oil found in Prudhoe Bay in 1968. During construction, engineers faced many issues, often due to extreme weather conditions. By

the end of 1977, the pipeline had transported its first barrel of oil, and many notable incidents have occurred since, such as maintenance issues and malfunctions as well as vandalism and sabotage from outside opposition, all resulting in leakage from the pipeline. The following is a reform act retrieved from

the Library of Congress, which was proposed to the 101st Congress in 1989 in an effort to reform the Trans-Alaska Pipeline System Authorization Act.

Summary: H.R.3277—101st Congress (1989–1990)
Introduced in House (09/14/1989)

Trans-Alaska Pipeline System Reform Act of 1989—

Title I: Trans-Alaska Pipeline System Fund and Liability—Amends the Trans-Alaska Pipeline System Authorization Act to repeal the limits placed on liability for oil pollution damages caused by a holder of a pipeline right-of-way. Declares that certain liability provisions of the Act shall apply only to incidents occurring before the enactment of this Act.

Title II: Trans-Alaska Pipeline System Trust Fund—Establishes the Trans-Alaska Pipeline System Trust Fund (TAPS Trust Fund). Imposes a specified fee on oil transported through the trans-Alaska pipeline, and directs the Secretary of the Interior (the Secretary) to deposit such fees into the TAPS Trust Fund for the safe and environmentally sound operation of the trans-Alaska pipeline system.

Title III: Improvement of the Trans-Alaska Pipeline System—Establishes the Presidential Task Force on the Trans-Alaska Pipeline System to: (1) conduct a comprehensive audit and review of the trans-Alaska pipeline system; (2) make recommendations to the President and the Congress; (3) function as a permanent forum for improved oversight and enforcement of safety and environmental laws related to the trans-Alaska pipeline system; and (4) report to the President and the Congress regarding the audit results. Requires an annual report to the President and the Congress.

Establishes the Trans-Alaska Pipeline Terminal Advisory Council to: (1) assist trans-Alaska pipeline operators and government officials in developing policies, permits, and regulations relating to pipeline facilities that may effect public health and safety and the environment; and (2) serve as a forum for industrial users, owners, and operators of terminal facilities to work cooperatively with local residents.

Conditions use and operation of pipeline and terminal facilities along the trans-Alaska right-of-way upon cooperation with the Advisory Council through frequent consultation, attendance at meetings, and by granting the Council access to all facilities and

requested documents and information. Directs the Advisory Council to submit an annual status report to the Task Force, the Governor of Alaska, and the Congress.

Title IV: Alaska Oil Spill Recovery Institute—Directs the Secretary to establish the Alaska Oil Spill Recovery Institute to: (1) research and implement oil spill cleanup and prevention technology in the arctic and subarctic marine environment; and (2) assess the long-term Exxon Valdez oil spill's effects upon the Alaskan environment and natural resources.

Directs the Institute to establish a Scientific and Technical Committee to advise its Board of Directors. Directs the Institute to submit an annual status report to the Governor of Alaska and to the Congress.

Title V: Penalties—Amends the Outer Continental Shelf Lands Act to increase the civil penalty for non-compliance with such Act to \$20,000. Directs the Secretary to adjust such penalty on a triennial basis to reflect any increases in the Consumer Price Index. Directs the Secretary to assess a civil penalty for any oil discharges occurring at various transit stages related to the trans-Alaska pipeline. Imposes joint, several, and strict liability upon the owners of oil for the full amount of penalties assessed for an oil discharge (or any threat of one). Sets a minimum civil penalty amount of \$1,000 per barrel of oil discharged.

Title VI: Provisions Applicable to Alaska Natives—Amends the Alaska National Interest Lands Conservation Act to declare that solely for the purposes of bringing oil pollution liability claims, all Federal interest in lands validly selected but not yet conveyed to Alaska Native Corporations are deemed to have vested in the respective corporations as of March 23, 1989.

Amends Federal law to direct the Secretary to report to the Congress the results of a study of the issues of recovery of damages, contingency plans, and coordinated actions in the event of an oil spill in the Arctic Ocean.

Title VII: State Laws and Programs—Declares that this Act does not preempt or affect State laws, programs, and authorities regarding oil pollution liabilities. Directs the President to consult with the affected States regarding any oil discharges.

Transistor Radio

For the engineer, December 23, 1947, is immortalized as the day of the invention of the transistor. Others may point to 1954 and the release of the Regency TR-1 transistor radio, but for the businessperson, it was the breakthrough Japanese transistor radio in 1957 that had the greatest impact on American business. The Sony TR-63 would be the first “pocket-sized” portable radio. For a few years, American manufacturers had dominated the transistor radio market, since it was Bell Laboratories that gave us the transistor. The transistor radio, however, proved a perfect product for Japanese manufacturers. The Japanese Ministry of International Trade and Industry had been searching for new industries to develop in Japan after the war, and it helped finance a \$25,000 licensing agreement for Tokyo Telecommunications—which grew from 7 employees to become Sony Corporation (originally Tokyo Tsushin Kogyo) with over 500 employees. Sony used its advantage in low labor costs to release the smaller, lower-priced TR-63 transistor radio to the American market.

The 1906 development of the vacuum tube had moved electronics a huge step forward, but its size and reliability limited its product application. After World War II, America’s largest industrial laboratory, American Telephone and Telegraph’s Bell Laboratories, started a research project to develop a better electronic switch and amplifier for the telephone. Following the goal-oriented research and development methods of Thomas Edison, this was an extension of earlier research on semiconductors. In 1947, the transistor came into being; the team of Bill Shockley, John Bardeen, and Walter Brattain would win a 1956 Nobel Prize for their work. Companies around the world wanted to develop products in which the new tech could be used. In 1954, Texas Instruments developed the first silicon transistor, which was picked up for military applications, but it wanted more profitable, commercial applications. A year earlier, Masaru Ibuka, cofounder of Sony, had traveled to the United States to study transistors and was able to purchase a license to produce them. Ibuka started a commercial product development team back in Japan

with his partner, physicist Akio Morita. Japan would emulate this strategy of buying or copying basic research to invest into product development in many industries.

Texas Instruments teamed up with Industrial Development Engineering Associates and Regency Electronics to manufacture the Regency TR-1, the first transistor radio, in 1954. The TR-1 was designed to be as small as possible, based on a market analysis of a 20-million-unit market. The TR-1 struggled with quality problems and a price tag of \$49.95 (over \$360 in today’s dollars). Yet, sales reached 100,000 per year. Raytheon’s 8-TP-1 and Sony’s TR-55 entered the market in 1955. The Raytheon radio had better quality and reliability but was larger and carried an \$80 price tag. Sony’s had the lowest price at \$39.99 and was the smallest; still, the sales remained around 100,000. The radio was not considered pocket-size yet. The Sony effort was a total failure, but as was typical of the Japanese product development model, it learned from its mistakes and introduced a new product quickly. The Sony TR-55 also lacked advertising because Sony was still a small company with limited capital. It advertised the product only in trade magazines. Sony looked to miniaturize its product and advertise more.

In 1957, it introduced the TR-63 to Americans, cracking the transistor radio market wide open. It measured roughly 4.5 by 3 by 2.5 inches and used a nine-volt battery. The company quickly got the price down to under \$25, which opened up more market. By 1962, the price was \$15. Sony advertised the radio as pocket-size, although it was a very uncomfortable fit. Sony also hired an advertising agency, and a cartoon character named “Atchan” was created to advertise the radio. Market success and low Japanese labor costs quickly brought competitors such as Toshiba and Sharp into the business. The transistor was the root of these electronic giants of today.

Many cultural forces combined to make the transistor radio a major commercial success. These included the huge youthful population segment (baby boomers), high disposable income after World War II, and the growing popularity of rock ‘n’ roll music. In addition, the Japanese learned marketing. They started to produce colorful and novel plastic cases to attract the youth market. They also produced radios with

corporate logos for the business promotional market. In many ways, the transistor radio business taught the Japanese how to be successful with products in the United States. The Japanese applied this simple business model to overtake market after market in the United States, but by the late 1960s, production had left Japan for Hong Kong because of lower labor costs there. Today, China is the major producer of transistor radios, although American Zenith held on to the upper end of the market for years. The transistor radio success inspired the Japanese to move into the American market with other products, including cars. The transistor radio today remains the most popular communications device in history, with estimates that 7 billion were produced.

TV Dinner

A TV dinner is a prepackaged, ready-made meal that can be reheated in the microwave or conventional oven. It usually consists of an individual portion of some type of meat, a vegetable and/or starch such as potatoes or rice, and sometimes a dessert. The idea for these meals came from a company called Maxson Food Systems that began making meals that could be reheated during airline flights in 1945. Swanson was the first to market frozen meals to the nation in 1954. With a surplus of turkey around the Thanksgiving holiday in 1953, Swanson decided to sell a frozen Thanksgiving meal and market it as a “TV dinner.” The meal was packaged in the same tray it would be reheated in.

In the 1950s and 1960s TV dinners were marketed to American women, many of whom enjoyed increasing disposable income and job opportunities, as labor-saving convenience products. (Stringer/Hulton Archive/Getty Images)

The TV dinner became immensely successful because of its convenience and because Swanson also cleverly linked its frozen dinners to a recently popular invention—television. TV dinners were introduced when family life was changing. More women were working for wages and looked for ways to save time on food preparation. These meals were also popular with bachelors who did not want to cook. Rising divorce rates in the 1970s and 1980s encouraged companies to market frozen dinners to single men.

Unimate/Industrial Robot

An unimate or industrial robot is an automated machine capable of completing factory tasks with mathematical precision. Its abilities range from welding metals to picking and placing parts of circuits, and more. These robots move on one or two axes, allowing them to handle specific operations with ease and rigor. The first known industrial robot was the unimate—a mechanical “arm” that welded metals on automobiles with more exactness and safety than human workers at the time. The device could effortlessly transfer all kinds of objects and material to their necessary destinations and thus guarantee that no more factory workers would be harmed in completing such tasks.

In 1956, American engineer George Devol of General Motors and business associate Joseph Engelberger originally designed the unimate as a literal mechanical arm. The unimate revolutionized the production industry, as it was the world’s first industrial robot. The device was a mechanical arm designed to complete factory tasks more easily and efficiently than the average worker. This robot was also designed to weld metal auto parts and die castings with more precision and safety; the job was hazardous for workers, as it released toxic fumes.

The machine weighs up to 4,000 pounds and consists of two large, connected boxes joined to a long arm. The robot is easily programmed and controlled. Today, the robot is even used to design other types of industrial robots. The unimate has six programmable axes of motility that allow it to adapt to manipulating many different kinds of metal parts. The unimate robot vastly increased production amounts and speed beyond what humans can do by hand.

Some of these industrial robots complete certain strategic actions repeatedly; these are called “repetitive actions.” They perform with extreme precision. Such robots require highly particular motion sensors to carry out their tasks and are programmed for a specific velocity and acceleration.

In 1962 George Devol and Joseph Engelberger founded Unimation, the world’s first robotics company. Victor Scheinman, from Stanford University, invented the Stanford arm in 1969—a multiaxis version of a unimate. His vision was to replace human

factory workers entirely. By the late 1970s, many U.S. industries had adopted the newer industrial robots, including General Motors, which had originally invented the unimate. The market for industrial robots erupted, and companies were established to appeal to potential buyers. While the robotic economy rose, Unimation, was sold to Westinghouse Electric Corporation for the price of \$107 million. Later, Westinghouse sold Unimation to Staubli Faverges of France in 1988. But it was mainly Japanese companies that excelled in the robotic market, producing the highest quality robots.

Universal Automatic Computer (UNIVAC)

The Universal Automatic Computer (UNIVAC) was one of the first commercial computers ever built in the United States. Before that, computers were created as one-off products to be used for particular jobs, and then the UNIVAC changed the game. The UNIVAC was intended to solve business and administrative problems, but its ability to collect and analyze data made it useful to its first buyer, the U.S. Census Bureau.

The UNIVAC had 1,000 words of retention, and each word had a number of decimal digits. It could handle numbers, equations, and problems that punch card machines could not. The UNIVAC also computed data regarding research and expenses. It was a business computer ahead of its time that paved the way for the laptops and computers that we use today.

The Universal Automatic Computer was created by Drs. John Presper Eckert and John Mauchly, the

inventors of the Electronic Numerical Integrator and Computer (ENIAC). After they left the University of Pennsylvania Engineering School, the U.S. Census Bureau asked them to create a machine that could help track the rapid increase of population at the end of the 1940s. The Universal Automatic Computer was essentially an upgrade or improved version of the Electronic Numerical Integrator and Computer.

The first UNIVAC cost approximately a million dollars to manufacture and was funded by investors such as Remington Rand Inc. In 1951, the first UNIVAC computer was delivered to the U.S. Census Bureau. The Prudential Insurance Company was the first commercial customer for the new computer.

The UNIVAC also helped pave the way to the era of big computer equipment common in the 1960s and 1970s. The computer was too costly for even major universities at the time, so it was most often bought by governmental organizations or corporations for business and administration purposes. In 1952, the television broadcast channel CBS used the UNIVAC to successfully predict the results of the U.S. presidential election in advance, claiming that Eisenhower would win. This achievement raised public awareness of technology and computers. The UNIVAC revolutionized the way we predict the patterns of many things and how we use technology and analyze data. The Universal Automatic Computer was also used to tabulate the 1950 U.S. population census as well as the 1954 economic census.

Fewer than 50 UNIVAC computers were made. Each one was about 25 by 50 feet in area and weighed around 16,000 pounds. Because the UNIVAC was difficult to manufacture, it was nearly impossible to keep up with the demand for its use. It was the main competition for IBM computers, which were easier to produce but were slower in performance.

The original UNIVAC is now displayed at the Smithsonian Institution. The UNIVAC computer foreshadowed our reliance on software today. It revolutionized technology and began the computer industry we now find indispensable.

Vaccines

A vaccine is a biological agent or preparation that, when introduced into a host, produces an immune response in the host. Vaccines are largely preventative, though medical science is exploring the possibility of therapeutic vaccines for diseases like cancer.

The word “vaccine” originally meant the introduction of cowpox disease into the human body to produce immunity to smallpox. Over time, it came to be applied to other methods of disease control that worked with the same principle in mind—namely to artificially induce immunity by inserting a version of the organism that works to prevent or ameliorate its dangerous symptoms.

The smallpox vaccine was introduced by Englishman Edward Jenner in 1798. Smallpox is an infectious disease of the blood system, nose, and mouth whose distinguishing characteristics are extensive skin rashes and blisters. It is called “smallpox” to distinguish it from the “great pox” known now as syphilis—which equally terrorized families at the time. During the 18th century, the mortality rate from this disease alone was roughly 35 percent, meaning that one in three people infected with smallpox died. Mortality was even higher among infants and young children. Those who did not die from it were typically impacted by lifelong symptoms such as blindness, pitted or “pockmarked” skin, and an overall weak condition. Smallpox is sometimes known by its Latin name “*variola*”; hence, the term “variolation” can be used interchangeably with “inoculation.”

By the 18th century, the treatment and eradication of smallpox became one of the humanitarian and “enlightened” measures of educated people on both sides of the Atlantic. The preventative possibilities of inoculation prompted many supporters both inside and

outside the medical community, including Enlightenment writers such as Voltaire and America's Benjamin Franklin, who lost one of his children to smallpox, to advocate broader use of the method.

Inoculation was not without its dangers. While it was known that infecting a person with a weakened form of the disease could provide immunity to smallpox, it was unknown precisely how this happened, and further, the procedure could cause harm or death in inexperienced hands. Examples abounded of patients dying after being inoculated, or the inoculated setting off an epidemic of smallpox within their local community. With these observations in mind and coupled with the fact that inoculation's greatest supporters were often progressive or "enlightened" people, their adversaries among clergy, doctors, and civil officials were deeply wary of the method if not outright hostile to it.

The first documented instance of inoculation in the 13 colonies occurred in Boston, Massachusetts, in 1721. The Puritan minister Cotton Mather had learned about the method over a decade before from one of his slaves, and he researched it. When an epidemic of smallpox broke out in 1721, he advocated for local residents to be inoculated. Mather assisted Boston physician Zabdiel Boylston, who inoculated nearly 300 in the city, with only six deaths. The 1721 outbreak in Boston was a watershed moment for inoculation in the Americas, as it demonstrated the preventative possibilities of inoculation and eased the consciences of some religious objectors.

By the 1840s, it had been determined that immunity gained from smallpox vaccination could weaken over time, meaning that each person needed to be periodically revaccinated to remain protected. The question of maintaining consistent and periodic vaccinations came to the forefront, and compulsory vaccination became a matter of intense social and political debate by the middle of the 19th century. Great Britain passed mandatory infant vaccination in 1853, with a number of continental European powers following suit. As the situation in the United States was more decentralized, the question of compulsory vaccination was left up to state legislatures. Massachusetts was the first to pass such measures for infants as far back as 1809. This type of legislation was enforced by requiring students entering public schools to provide certificates of vaccination.

By the first decades of the 20th century, 5 states prohibited compulsory vaccination outright (Arizona, Utah, Minnesota, and North Dakota), while 10 states and the District of Columbia had a system for compulsory vaccination in place. Vaccine policy was a battleground between medical reformers desiring to "uphold the greater good of the community" and those fearful that compulsion stood in the way of their civil right to freedom of conscience. This matter was only partially resolved in the landmark Supreme Court case of *Jacobson v. Massachusetts* (1905), where the ruling was in favor of state legislatures and compulsory vaccination laws based on the principle that individual rights sometimes needed to be curbed by the power of the state to protect the common welfare. *Zucht v. King* (1922) upheld this decision with regard to vaccine certificates and admission into schools.

While the term "vaccine" initially referred to the smallpox vaccine, French scientist Louis Pasteur successfully proposed in 1881 that the term also be applied to the latest advances in inoculation against other diseases, such as anthrax and rabies, as homage to the pioneering work of Edward Jenner. While Jenner's vaccine substituted another, less violent disease as a preventative measure, the new generation of vaccines created during the late 19th century used a specimen of the disease itself weakened in a laboratory environment. This advance allowed a number of new vaccines to be developed over the turn of the 20th century: tetanus (1890), typhoid fever (1896), diphtheria (1921), and pertussis or "whooping cough" (1927).

The development of medicines in professional laboratories also increased the role of pharmaceutical companies in the research, production, and distribution of vaccines. The Second World War, which sent American soldiers to fight in varied environments across the world, also aided in the development of new vaccines. The military developed the first vaccine for influenza during the 1940s, where researchers gained experience that they applied to creating new vaccines during the postwar period. One of these was Jonas Salk, who developed the polio vaccine in 1952. American physicians Thomas Chalmers Peebles (1921–2010) and John Franklin Enders (1897–1985) worked on isolating diseases and developed a vaccine for measles at Children's Hospital in Boston in 1963. Enders

is known as the “Father of Modern Vaccines” because of his pioneering work isolating the polio strain, for which he shared the Nobel Prize in 1954.

The most prolific vaccine researcher of the 20th century was the American microbiologist Maurice Hilleman (1919–2005). During the span of a long career in medicine, he created over 36 vaccines, of which 8 are part of the list of 14 vaccines currently recommended for every person. As a researcher at E. R. Squibb & Sons, a pharmaceutical company headquartered in New York City, he developed a vaccine against Japanese B encephalitis that greatly aided the treatment of soldiers fighting in the Pacific Theatre during the Second World War. As head of virus and cell biology research at Merck & Co. from 1957 to 1984, Hilleman researched a vaccine against mumps, measles, hepatitis B, chicken pox, and pneumonia, among others. Hilleman and his associates developed the MMR vaccine in 1971, which combines measles, mumps, and rubella in one single shot.

The global development and distribution of vaccines is a major political and humanitarian effort that gained momentum after 1945. The World Health Organization, an agency of the United Nations founded in 1948, has a significant role in the development of vaccines and their administration. It targeted smallpox for worldwide eradication, which ended successfully in the late 1970s due in large part to greater access to vaccines.

Vaccines continued to be developed into the 21st century, often in response to challenges brought by resurgent or emerging diseases. These include rotavirus (1998), human papillomavirus (2006), and enterovirus 71 or “hand, foot, and mouth disease” (2013). In 2003, the first nasal vaccine for influenza was approved in the United States. The future of vaccines may hinge on the fact that they only prevent a small number of diseases at present. Traditional vaccines, which use either weakened or dead versions of the disease organism, cannot protect against certain mutations or changes in the disease. “Third generation” vaccines, which make use of genetically engineered bacterial DNA inserted into the cells of the body to create new antigens to combat pathogens, will be the next generation of vaccinations. Currently, experiments with DNA vaccines are being applied to West Nile virus and bird flu variants. The ethical questions behind altering DNA

and how such vaccines will be developed, distributed, and marketed remain a matter for future debate.

However, traditional vaccines continue to be a source of conflict in American society. Part of this is the legacy of the anti-compulsory-vaccination debates of the late 19th and early 20th centuries that uphold vaccination as a matter of individual conscience. Some express concerns over the “commodification” of vaccines by companies looking to profit rather than maintaining a suitable safety margin against potential side effects. The highly discredited link between the MMR vaccine and autism proposed in a 1998 medical article (later fully retracted in 2010) still remains the foundation for a new movement of anti-vaccination literature, despite the utter lack of evidence of any such link. Public health officials and parents who do vaccinate their children point out that parents who choose to not vaccinate in the face of overwhelming evidence of vaccination safety endanger not only their own children but all children too young to be vaccinated.

Vaughan, Dorothy (1910–2008)

Mathematician Dorothy Vaughan was also the first African American woman to supervise a group of employees at the National Advisory Committee for Aeronautics’s (NACA) Langley unit.

Vaughan was born on September 20, 1910, in Kansas City, Missouri. Her family moved from Missouri to West Virginia, where she graduated from Beechhurst

Dorothy Vaughan, Leslie Hunter, and Vivian Adair in 1950, working as mathematics calculators for Langley Research Center, a precursor to NASA. Vaughan was Langley's first black, female supervisor. (Smith Collection/Gado/Getty Images)

High School in 1925. Her good grades earned her a full-tuition scholarship to Wilberforce University, a historically black college in Wilberforce, Ohio. She graduated with a bachelor of arts in mathematics at age 19 in 1929.

The Great Depression also hit the nation in 1929. Therefore, although her professors at Wilberforce recommended her for graduate studies in mathematics at Howard University, she opted to earn a degree in education and become a teacher, as it was a stable career for black women with college degrees. Her income allowed her family to survive the depression. In 1932, she married Howard S. Vaughan Jr., with whom she had six children. She taught mathematics at Robert Russa Moton High School in Farmville, Virginia. In 1941, President Franklin Roosevelt signed Executive Order 8802 that prohibited racial discrimination in the national defense industry. Roosevelt believed the order would

ensure that the entire American effort, regardless of a person's race, was geared toward World War II, a war he believed the United States would win in the air.

Two years later, Vaughan applied to NACA's aeronautical laboratory in Langley, Virginia. The laboratory required mathematicians, or "computers," to meet the increasing demand for processing aeronautical data and preferred to hire women because they could be paid lower wages than men. The new "colored" mathematician hires were assigned to the segregated West Area Computing unit. These women's contributions spanned every area of research at Langley.

In 1949, Dorothy Vaughan was promoted to be the supervisor of the West Area Computing unit, which had been previously headed by white women. The West Area Computers continued as an all-black, all-female group. Members were required to use segregated bathrooms and eat in segregated cafeterias.

Vaughan was NACA's first black supervisor and one of the few women supervisors there. She was a strong advocate for the women not only in West Computing but in the entire NACA organization. Department heads and the engineers put stock in her recommendations regarding which women were best for particular projects.

Noted physicist and mathematician Katherine Johnson also worked for the West End Computers branch of NACA. Johnson was recognized as particularly skilled in computing celestial navigation, rocket trajectory calculations, and calculations for backup plans for Apollo and Space Shuttle program flights. She also contributed to the calculations for Mars missions.

Mathematician Mary Jackson also worked with the West End Computers, and in 1958, when NASA desegregated, she became the agency's first female black engineer.

Vaughan remained the head for West Computing until 1958, when NACA reformed into the National Aeronautics and Space Administration (NASA). Segregation in NASA was abolished in 1958, which meant the closing of the West Computing unit and all other segregated units. Dorothy and the women in West Computing joined the new Analysis and Computation Division (ACD). In 1961, Vaughan transferred to digital computing as NASA phased out human computers with electronic computers. She mastered programming in FORTRAN and made contributions to the Scout Launch Vehicle Program. Scout missiles were designed as launch vehicles for satellites and proved so successful that they were used from 1964 to 1991.

She retired from NASA in 1971 and died in 2008 in Hampton, Virginia. She was 98 years old. In her retirement, she had volunteered as a missionary for the African Methodist Episcopal (AME) Church.

Vaughan was largely unknown until the 2016 publication of *Hidden Figures*, a book about the black female NASA mathematicians. A film of the same name that year brought further public attention to Vaughan's importance.

Vocoder

Invented at Bell Labs, the vocoder is a mechanism created to analyze and synthesize the human voice and translate it to an audio data compression. This can be used to encrypt, transform, and compress voices. The vocoder is known as a part of the "voice codec," another term for "speech coding." The mechanism was first developed in 1928 by an engineer named Homer Dudley. It was first presented to the public at the AT&T Building at the 1939 World's Fair as a machine for producing recognizable speech over a distance.

Radio companies were interested in vocoders because they could compress audio data to reduce transmission bandwidth. The way the vocoder works is, it takes in input from a multiband filter and passes it through an envelope filter, which takes high-frequency signals and produces an output. From there, the output is sent to a decoder. The decoder then takes the applied settings from the filter and resynthesizes the sound.

The vocoder was used as a communication method during World War II, but it is now used mainly in electronic music.

Voyager Spacecraft

As of 2017, the Voyager mission was the most scientifically productive space investigation yet launched by the National Aeronautics and Space Administration (NASA). Both the *Voyager 1* and *Voyager 2* spacecraft (unmanned probes) sent back comparatively close-up images of planets and moons in the solar system that could previously be seen only as specks of light on the most powerful Earth-based telescopes. After the conclusion of the mission, the probes darted in opposite directions toward the edges of the solar system on their way to interstellar space.

The Voyager spacecraft were nearly identical. Each had a puck-shaped frame about 6 feet in diameter, 10 instruments for gathering scientific data, a communications antenna for sending data to Earth, a computer to run on-board systems, a high-gain dish about 12 feet in diameter for receiving command signals from Earth, a power generator that harnessed electricity from heat given off by several kilograms of plutonium-238, and various types of cameras. Each craft carried an identical gold-plated record of sounds and images of Earth as well as a map showing Earth's location. Scientists hoped that aliens would one day find these, perhaps millions of years in the future, and learn about Earth.

Both probes were launched from Cape Canaveral in 1977, but *Voyager 2* was launched two weeks before *Voyager 1*. NASA chose the names of the probes based on the order that they would reach Jupiter and Saturn. *Voyager 1* followed a shorter and faster route and passed *Voyager 2* in the asteroid belt between the orbits of Mars and Jupiter.

Voyager 1 reached Jupiter in 1979 and sent back clear images of the planet and its moons. Some of the most significant discoveries included volcanic eruptions on the moon Io, linear features on the moon Europa, and a dark ring within the rings of the planet. *Voyager 1* then used the gravity of Jupiter to propel itself toward Saturn.

Voyager 2 reached Jupiter four months later. Many of the images gathered by *Voyager 2* were similar to those gathered by *Voyager 1*. For example, *Voyager 2* also observed the volcanic activity on Io, although in much greater detail. *Voyager 2* made one significant new

discovery when it found a satellite (a small moon later named Adrastea) close to Jupiter's rings. *Voyager 2* then used a gravitation assist to slingshot toward Saturn.

Voyager 1 reached Saturn in 1980 and sent back images of the planet and its moons. *Voyager 1* revealed that the planet's rings were much more complex than previously known. Having completed its mission, *Voyager 1* used the moon Titan's gravitational pull to propel itself toward the edge of the solar system. *Voyager 2* arrived at Saturn a few months later and sent images that corroborated *Voyager 1*'s data.

Since the two outer planets were in a certain alignment that would not occur again for another 150 years, NASA decided to extend *Voyager 2*'s mission. *Voyager 2* reached Uranus in 1986 and Neptune in 1989. It discovered 10 new moons orbiting Uranus. And, it documented giant storm systems on Neptune, a dark spot on the planet, and six new moons. Finally, with a gravity assist from Neptune, *Voyager 2* propelled itself toward the edge of the solar system.

Before the Voyager mission, NASA had launched other long-range probes. However, none of them had remained in operation long after their missions were completed. In contrast, the Voyager craft continued to transmit scientific data from the edge of the solar system for decades. In fact, instrument readings on board *Voyager 1* in 2012 reported a significant drop in the number of solar wind particles and a simultaneous rise in interstellar cosmic rays, which convinced scientists that the probe had left the solar system and entered interstellar space; it was the first documented case of a man-made object reaching this milestone. Estimates of the dates of demise of the on-board battery power of both probes range from 2020 to 2030, about half a century after they left Earth.

Wise, Brownie (1913–1992)

Brownie Wise made her mark on history by developing innovative new methods of marketing and selling products and motivating sales teams at a time when women working for wages was practically unheard of. She was the first woman to be featured on the cover of *Businessweek* thanks to the at-home sales model she created for the Tupperware Home Parties company, which many other companies, including Avon and Mary Kay Cosmetics, use today.

Born in 1913, in Buford, Georgia, Brownie Mae Humphrey's working parents divorced when she was young. Because her mother's job as an organizer for a hatmaker's union required her to travel, Wise spent much of her childhood in Atlanta, Georgia, with an aunt.

Wise's leadership abilities became evident when she was 14 and had begun giving speeches to the union members her mother had been sent to meet. She left school in eighth grade to accompany her mother on business trips. At the age of 18, Wise attended a YMCA camp for career-minded girls in hopes of becoming a writer or an illustrator.

Wise's artistic ambitions were rewarded in Dallas, Texas, in 1936 when she won a contest to paint a mural at the Texas Centennial. While there, she met Robert W. Wise, who had been sent to oversee the Ford Motor Company's exhibit. The couple married in 1936 and relocated to Detroit, where their only child, Jerry Wise, was born in 1938.

Though Wise was home with her child, she did manage to realize her other ambition—to write professionally—by contributing to a *Detroit News* column in which submitters wrote about their lives under fancifully assumed pen names. The lovingly rendered details of Wise's literary double, "Hibiscus," bore no resemblance to Wise's own self; sadly, what they *did* reveal was a woman whose idealized depictions of a loving husband and genteel childhood spent at her grandmother's Southern mansion provided an escape from the reality of her working-class origins and unhappy marriage to a violent alcoholic.

When the Wises divorced in 1942, Brownie worked two jobs—one as a saleswoman in a clothing shop, the other as a secretary. She also began selling for Stanley Home Products, one of the originators of

the so-called home party demonstrations, and Wise soon became a top seller.

In the late 1940s, Tupperware, which was already being sold in department stores, appeared on Wise's radar. Thinking its need to be "burped" made it the perfect home demonstration product, Wise left Stanley to start her own company: Tupperware Patio Parties.

In 1948, Wise phoned Earl Tupper (1907–1983), Tupperware Products's founder, and informed him of her company's success selling Tupperware. Tupper, who had already attempted his own unsuccessful version of a home party division, soon joined forces with Wise, and in 1950, Wise, her son, and her mother left for Florida, where Tupper appointed Wise vice president. Based on Wise's plan, Tupperware was withdrawn from retail stores in the early 1950s, and home selling became its primary market.

Wise then began empowering women in the home. The 1950s were a time when women were struggling to find a balance between work and family. So, Wise created Tupperware Home Parties Inc., and turned homemakers into entrepreneurs. At the lowest level were the dealers, who demonstrated and sold the product at home parties. Successful dealers were able to move up to the manager level, where they would oversee and train their own group of dealers.

In a time when women did not receive much recognition, Wise also developed a newsletter that celebrated top dealers. She held a yearly convention called the Jubilee where housewives could escape their domestic lives and celebrate their success, learn new sales techniques, and win extravagant prizes. All of this served to build not only women's self-confidence, but also their loyalty to Tupperware.

Tupperware's meteoric success and the resultant attention the business world lavished on Brownie Wise soon wore thin on Earl Tupper. Despite the fact that he had originally been on board with his company's extensive promotion by Wise, she received so much publicity that Tupper became jealous. Wise was fired without reason. She went on to start four more home party companies, but none of them were as successful. She died in Kissimmee, Florida, in 1992.

Xerox Corporation

The Xerox Corporation began as the Haloid Company in 1906 in Rochester, New York. It “offer[ed] products in office equipment and furniture” and aimed to aid businesses with technology and services with more intelligent document management. It offers printers, color and black-and-white copiers, and digital presses, plus the supplies, software, and support that go with them.

The Haloid Company did not become Xerox until 1961. It first became Haloid Xerox in 1958, a nod to its banking on the dry printing process. “Xerox” is a word coined by the company from two Greek words meaning “dry writing.” The company was successful, specializing in photographic paper and lithography. It had even been able to make a profit during the Great Depression and thrived during World War II. However, its market share decreased as the war wound down, and its president, Joseph C. Wilson (1909–1971) began to search for a new product.

Wilson was the grandson of one of Haloid’s founders and the son of Joseph R. Wilson, the president who took Haloid public in 1935. He became president of Haloid in 1945. He had John Dessauer search for a viable new product. This led to an interest in Chester Carlson’s “xerography” process. It made photographic copies on plain paper rather than coated paper. Wilson made a deal with Carlson, eventually getting most of his patents and the rights to his machine. It was a bet that paid off and made many Rochesterians “Xerox millionaires.”

Wilson and Dessauer went to Battelle Laboratories in Columbus, Ohio. Battelle was impressed with the men’s photographic copy process, though officials at the company worried that it might not be commercially viable. Wilson contacted Sol Linowitz, a Rochester attorney who negotiated with Battelle. The price

to Haloid was \$25,000 per year and 8 percent of the revenues from “electrophotography.”

The first public demonstration of xerography took place in 1948 on October 22. It was the 10th anniversary of Chester Carlson’s invention of electrophotography. Wilson unveiled a red box that made one copy in one minute. It was a promise of things to come; Wilson’s father predicted that the Xerox machine would be commercially viable by 1950—but it was not. Wilson began to secure new patents and to gain sole rights to Carlson’s work. Because the original patent would expire in 1957, these steps helped insure that Haloid would be in a good position when it did.

In 1955, Xerox produced Copyflo, the first copier that used xerography. Copies were made from microfilm. It was a start and gave hope to those who believed in the company. The company put \$75 million into xerography development between 1947 and 1960. That was twice its earnings. In today’s dollars, it was about \$530 million. Wilson bet the company on the success of Xerography—he even mortgaged his home.

Wilson won the bet, and the company entered a long period of profitability. In 1958, Haloid and Rank announced a merger to serve both the United States and Europe. In September of the next year, the 914 was unveiled. It was the first true Xerox machine providing rapid copies on normal paper. Xerox continued to be a technological innovator, coming out with one innovation after another.

The center of these innovations was the Xerox Palo Alto Research Center, generally called the PARC. It opened a year after Xerox moved its corporate headquarters to Stamford, Connecticut, in 1969. The PARC is near Stanford University, and Xerox hoped to draw on the school’s scientific resources for development aid. In 1973, Xerox developed the very first personal computer. The company named it the Alto. A number of innovations emerged from the PARC in its first decade of operation, including the first mouse, a bitmapped display, and a graphical interface. The result was the 8010 Star computer. Xerox’s Star was developed 8 years before IBM’s and more than 10 years before Steven Wozniak and Steve Jobs developed their first Apple Computer. Indeed, Wozniak and Jobs co-opted many of the Star’s features, including the use of folder icons and graphic user interfaces, the two button mouse, and e-mail.

While Xerox was at the forefront of personal computer innovation in the 1970s, the company rejected the Alto design and virtually ignored the work done at PARC. By the time Xerox realized its mistake in the 1980s, the Apple II, which used a mouse-central interface, had changed the computer market. Xerox never seriously competed in the home computer market though it had been a leader in business technologies for decades. The only major innovation from the PARC on which Xerox made great commercial profit was the laser printer.

Primary Document: Patent for Xerography (1956)

Reproduced here are excerpts from the patent for xerography, which is a photocopying technique. There are many ways to produce photocopies, including more recent developments that allow for advanced digital photocopying. However, the discovery of xerography is what led to the very first commercial photocopier as we know it today by Xerox, making this technique fundamentally more important than others that have been developed since. This document, filed on May 2, 1956, contains a detailed technical description of the process as it was originally invented by Schaffert Roland for the Xerox corporation.

COLOR XEROGRAPHY Roland M. Schaffert, Columbus, Ohio, assignor, by mesne assignments, to Haloid Xerox Inc., Rochester, N.Y., a corporation of New York Filed May 2, 1956, Ser. No. 582,107
2 Claims. (Cl. 96-1) This invention relates in general to xerography and in particular to the xerographic reproduction of color images.

In the art of xerography it is usual to record and reproduce by electrical means a black and white copy of an original scene, document or the like. Such xerographic reproduction has been brought into commercial use for the making of line copy images and, to a certain extent, for continuous tone reproduction. At the present time, however, there is no system commercially available for producing colored xerographic prints. It is, therefore, an object of the present invention to provide means, method and

apparatus for the production of full colored xerographic prints.

It is a further object of the invention to provide means, methods and apparatus for two or more color xerographic reproduction and for the addition of other colors thereto.

It is an additional object of the invention to provide a new method for reproduction of xerographic images corresponding to two primary colors of light.

It is a still further object of the invention to provide new color xerographic apparatus comprising a light sensitive xerographic member characterized by having two separate sensitive xerographic layers each selectively sensitive to exposure by means of a different primary color.

It is a still further object of the invention to provide new means, methods and apparatus for color xerography whereby a xerographic print or reproduction in two colors can be produced with a single exposure to light of mixed primary colors.

In accordance with the present invention, a plurality of photoconductive layers of selected conductive sensitivity to light of different primary colors are simultaneously exposed to a projected light image of mixed primary colors. For example, a plurality of photoconductive layers may be superposed, one on top of the other in laminated configuration, and a light image of mixed primary colors may be projected onto the array of photoconductors from one side thereof so as to pass selectively through the first of the photoconductors in reaching the last of the

photoconductors. An electric field is applied through the photoconductive layers while they are exposed in this manner so as to produce a plurality of developable xerographic latent images which may be developed and superposed to form a two-color or full color xerographic reproduction.

AND:

What is claimed is:

1. The process of color xerography comprising projecting a light image consisting of a pattern of light and shadow of at least a first and a second primary color onto and through a first photoconductive insulating layer adherent on a substantially transparent conductive member and onto a second photoconductive insulating layer adherent on the opposite side of said member while maintaining an electric field through said layers to form an electrostatic latent image thereon, said first photoconductive layer being conductively sensitive to light of at least one first primary color and both substantially transparent to and substantially insensitive to light of at least one second primary color, said second photoconductive insulating layer being conductively sensitive to light of at least said second primary color, one of said photoconductive layers consisting essentially of a dispersion in a transparent insulating binder of a material selected from the group consisting of zinc oxide, cadmium sulfide, mixed zinc sulfide cadmium sulfide, zinc sulfide, zinc selenide and titanium dioxide, and the other of said photoconductive layers consisting essentially of a material selected from the group consisting of vitreous selenium, a dispersion of mixed cadmium selenide-zinc selenium in a transparent insulating binder, a dispersion of mixed lead oxide, zinc oxide in a transparent insulating binder, and a dispersion of mixed mercuric sulfide-zinc oxide in a transparent insulating binder, developing said

latent images with colored finely divided particles of colors complementary to said first and second primary colors respectively, and super-posing the developed color image for the first primary color with the developed image for the second primary color on a common support layer.

2. The process of color xerography comprising projecting a light image consisting of a pattern of light and shadow of at least a first and a second primary color onto and through a first photoconductive insulating layer adherent on a substantially transparent conductive member and onto a second photoconductive insulating layer adherent on the opposite side of said member while maintaining an electric field through said layers to form an electrostatic latent image thereon, said first photoconductive layer being conductively sensitive to light of at least one first primary color and both substantially transparent to and substantially insensitive to light of at least one second primary color, said second photoconductive insulating layer being conductively sensitive to light of at least said second primary color, said transparent conductive member being substantially transparent to the primary color of photosensitivity of said second photoconductive insulating layer and substantially opaque to the primary color of photosensitivity of said first photoconductive insulating layer, one of said photoconductive insulating layers comprising vitreous selenium and the other of said photoconductive insulating layers comprising zinc oxide in a transparent insulating binder, developing said latent images with colored finely divided particles of colors complementary to said first and second primary colors respectively, and superposing the developed color image for the first primary color with the developed image for the second primary color on a common support layer.

Yalow, Rosalyn Sussman (1921–2011)

Nobel Prize–winning scientist Rosalyn Sussman Yalow developed the radioimmunoassay, a medical research tool that detects hormones and other proteins

by using radioactive markers. The process allows scientists to study the human endocrine system and treat diabetes, cancer, and thyroid disease.

Yalow was born on July 19, 1921, in New York City. Her parents were first-generation immigrants

Rosalyn Yalow, 1977 Nobel Prize winner for medicine, was an important advocate for the inclusion of women in science. (Bettmann/Getty Images)

from Eastern Europe. From a young age, Yalow was a prodigy in math and chemistry. In high school, her chemistry teacher encouraged her to enter the women's Hunter College, now City University of New York, as a chemistry major.

In 1939, Yalow attended a seminar presented by the famous nuclear physicist Enrico Fermi. Yalow found his discussion of the newly discovered nuclear fission process fascinating. Marie Curie further inspired Yalow, who switched her major to physics so she could study radiation and fission. She next applied to many graduate schools but was refused because she was a Jewish woman. Finally, she made a deal with Columbia University. She was able to take graduate-level classes if she agreed to take the stenography class and

work as a secretary for one of the physics professors. By January 1941, she was ready to quit. Fortunately, in February, the University of Illinois accepted her application, and she started there that fall.

On Yalow's first day at the University of Illinois, she met a man, Aaron Yalow, who would eventually become her husband. Aaron was a nuclear physics graduate student who also had an interest in medicine. Rosalyn Yalow was the only female student among the 400 male engineering students and the first one since 1917 to be accepted into the university. She finished her PhD in 1945 and moved back to New York to teach physics at Hunter College.

Aaron moved to New York a few months later and started to work at Montefiore Hospital in the Bronx. It

was through his work connections that Rosalyn Yalow was invited to start the first radioisotope service at the nearby Veterans Administration (VA) Hospital. Though this service was started in a room the size of a janitorial closet, it produced many groundbreaking publications on the medical application of physics and was replicated in many hospitals across the country. Yalow initially started as a part-time consultant and joined full time in 1950.

With Dr. Solomon A. Berson, Yalow published hundreds of scientific papers on radioimmunoassay. Berson died after they worked together for 22 years. The Nobel Prize committee could not recognize his contribution because it did not make posthumous awards. Yalow memorialized the laboratory they shared by renaming it the Solomon A. Berson Research Laboratory.

The radioimmunoassay, while winning the Nobel Prize for its incredible contribution to medical science, works on a relatively simple concept. It starts with a radioactive particle of iodine being attached to an antigen, which is a small and unique block of molecules found on most things in the bloodstream. Antigens are “marked” by the body with an antibody, a larger and Y-shaped protein that is specially made for each type of antigen. If the antigen is harmful to the body, it will signal the immune system to attack and destroy anything marked by the antibody.

Yalow and Berson’s discovery was to take a known amount of radioactive antigen and an unknown amount of a patient’s antigen and mix them in a solution of a known amount of an antibody. The antibody did not distinguish between the radioactive and nonradioactive antigens and would bind both of them proportionally. In other words, if there are two radioactive antigens for every nonradioactive antigen, the bounded antibodies will reflect this ratio.

Yalow was driven to find a treatment for her husband, who was diabetic. One of the first hormones they investigated was insulin. Yalow and Berson could have made a fortune from the commercial applications, but they did not apply for a patent. Instead, they preferred that other researchers use their discovery to make progress in treating diseases—and it is for this reason that Yalow was awarded the Nobel Prize in Medicine. She retired from the VA in 1991 and passed away on May 30, 2011.

2. The Post–Cold War Era (1980–1999)

OVERVIEW

The post–Cold War years saw the flowering of technology and innovation after a number of technological advances were released from the cocoon of military secrecy. The decades of the 1980s and 1990s signaled the death of several existing industries and generated unimaginable wealth in others. It was the era in which most people would come to know the names of Bill Gates and Steve Jobs, but few had ever heard of Tim Berners-Lee, who made it all possible.

Along with astounding advances in technology, science, consumer electronics, and home entertainment, the 1980s and 1990s also saw the proliferation of two major myths: the “paperless office” and the “millennium meltdown.” The era also ushered in the plague of computerized identity theft and introduced a nasty new four-letter word into the language: “hack.” In short, the post–Cold War years became a golden age for computers, consumers, and con artists.

Lifting the Veil

Not only did technology itself blossom between 1980 and 1999, but the post–Cold War years saw the *rate* of technological innovation accelerate exponentially. To many, the rapid advance of innovation was miraculous. For some, it was immensely profitable.

However, others were confounded by the dizzying rate of obsolescence. In the post–Cold War age of technological advances, it seemed that as soon as a consumer bought a new piece of electronics, it was outdated almost immediately, becoming an embarrassment to the purchaser who had so recently beamed with pride over that same acquisition.

The post–Cold War years also began hurtling toward the new millennium with a proliferation of choices. This was said by experts to instigate a perpetual state of buyer’s remorse about whether it was the right choice to buy this cereal or that cell phone plan, that laundry detergent or this laptop.

While the technological advances of the post–Cold War years in the 1980s may appear quaintly dated today, they actually signaled the biggest socioeconomic upheaval since the Industrial Revolution. The post–Cold War information age was a product of the Digital Revolution, or the advancement of technology from analog and mechanical devices to digital, electronic circuits. Digital information is recorded as a series of the numbers 1 and 0, to show that a signal is either positive (1) or nonpositive (0).

Those innovations took place only after the veil of military secrecy during the Cold War was lifted. When that happened, amazing things were revealed.

United States vs. USSR

The Cold War was a time of ideological conflict, military tension, and global political competition that followed World War II, lasting from the late 1940s until the 1990s. The struggle was essentially between the United States and the Western world against the Union of Soviet Socialist Republics (USSR) and the communist Eastern Bloc.

In a global variation of the adage that “the enemy of my enemy is my friend,” the United States and Soviet Union were allies against Germany during World War II, but growing tensions revealed that they had vastly different visions for the reorganization of postwar Europe. As the Soviet Union held eastern

European countries behind an “Iron Curtain,” the goal of the United States was to contain the spread of communism around the world.

With the ever-present threat of global thermonuclear war hanging over their heads, the United States and USSR did not clash directly. Instead, they built alliances, engaged in espionage and counterespionage, deployed forces strategically, squared off economically, and fought a propaganda war. They vied for the hearts and minds of the “Third World,” competing not only in technological areas such as the “Space Race” but also in fields like athletics during such events as the Olympic Games.

Ripple Effect

A small incident in 1980 led to a huge ripple effect in which the Cold War steadily decelerated. Behind the Iron Curtain, Polish shipyard workers went on strike, forming the Solidarity Union led by the charismatic Lech Wałęsa. Simmering resentments came to the surface in other communist-controlled countries.

In 1985, Mikhail Gorbachev became the leader of the Soviet Union, declaring a policy of glasnost (“openness”) and perestroika (“restructuring”). Through the 1980s and 1990s, one event followed another as Chinese protestors demonstrated in Tiananmen Square for reforms in China, East Germany allowed unrestricted migration to West Germany, former Soviet-controlled countries like Poland and Hungary declared non-Communist governments, and the Berlin Wall was demolished in 1989. With the abolishment of the Soviet Union in 1991, the Cold War was, for all intents and purposes, grinding to a halt.

ARPANET to Internet

During the Cold War, there had been a dramatic expansion of state-funded scientific and technological research on both sides. The governments of both the United States and USSR encouraged and supported technological projects that were kept under wraps, subject to restrictions said to be due to national security.

The obvious research areas were in military weaponry and the Space Race, but Cold War-era research

also affected areas such as agriculture, biologicals, chemistry, and medicine. However, the greatest impact would come in the field of computer science.

The end of the Cold War allowed many technologies that were formerly military secrets to become declassified and open to the public. The area of greatest magnitude—many might say revolutionary—was a system created by the Pentagon to keep in touch following a nuclear war. It was called ARPANET, short for “Advanced Research Projects Agency Network.”

During the Cold War years, ARPANET had been funded by the Advanced Research Projects Agency of the U.S. Department of Defense. When restrictions were lifted, the public would come to know it as the Internet. By that name, it took over the world.

America (and Everyone Else) Online

A few individuals started utilizing the Internet as soon as it opened to the public in the 1980s, with a much larger user group joining in the 1990s. Even then, people who used the Internet by going “online” in 1995 constituted only about 20 million users, or less than one-half percent of the world’s population at the time. They were mostly from the United States or a few other Western countries.

That figure grew exponentially in successive years to the point where the number of users was virtually impossible to track. Devices requiring Internet access would become common all over the world by the twenty-first century.

Central to this revolution was the mass production of digital logic circuits and derived technologies that enabled widespread use of computers, digital cellular phones, and the Internet.

A clearer picture of the post-Cold War era that began in the 1980s can be seen in a chronological look at the technological advancements that burst forth in computers. In 1982, the IBM personal computer (PC) allowed individuals to have data-processing devices to use at home or in a small office setting.

In 1983, the Global Positioning System, or GPS, was opened for use by civilian aircraft. It began a trend that led to Geographic Information Systems (GIS) and mapping tools used at first by entities like state and local governments, ultimately finding a place on auto

dashboards with a pleasant electronic voice telling drivers where to turn.

By 1984, several industries were in the process of being flattened by the advent of the compact disc read-only memory (CD-ROM), an optical-based disc that contains data but is usually neither writable nor erasable by the consumer. It signaled the demise of floppy discs for computer data storage as well as music on vinyl records and cassette audiotapes. It would soon overtake videotapes in the form of digital video discs (DVDs).

Meanwhile, that same year, flash memory was finding its place in small electronic devices. Digital cameras, cellular telephones, and the rise of the laptop computer would all come to rely on flash.

Start the Revolution

Although many people today might find it hard to believe, the World Wide Web was not always something that was simply “there,” like air. It was, in fact, something that had to be invented. That was accomplished in 1989 by Tim Berners-Lee, an Englishman working in Switzerland at CERN (Conseil Européen pour la Recherche Nucléaire, or European Council for Nuclear Research).

CERN had been established in 1954, during the frozen depths of the Cold War, but some of its greatest triumphs took place in the post–Cold War years of the 1980s and 1990s. These include the discovery of W and Z bosons (1983), work with light neutrino families at the Large Electron-Positron Collider (LEP) in 1989, and the creation of antihydrogen atoms (1995).

In 1988, while working on networking computers at CERN, Tim Berners-Lee began discussing a possible linked information system with his colleagues. By the end of 1990, his idea was implemented as the World Wide Web with its Hypertext Transfer Protocol (HTTP) and Hypertext Markup Language (HTML). Generally known simply as the “Web,” it revolutionized the world for business, communications, and individuals around the globe.

Through the 1990s, getting online entailed a complicated configuration and the aid of telephone equipment. With the breakup of the Bell System in 1984,

new telephone providers proliferated. Microwave links began to spring up along major corridors to provide service. Fax machines replaced telex in the 1980s. Answering machines evolved into voice mail.

Soon, even the advances in telephone technology veered in another direction as dial-up online service gave way to more advanced Internet connectivity in the 2000s.

Rise of the Luggables

For many people, the personal computer became a window on the world, bringing a wealth of information that was previously unimaginable to their fingertips, right in the comfort of their home or workplace. But others sought to keep their computers with them as they moved about the larger world beyond their house or office. Enter the laptop.

First called “luggables,” the folding units included a display and keyboard and were meant to travel, though they had limited battery life and had to be plugged in to both a power source and Internet connection wherever they were to be used. Due to their size and weight, today these early laptops are almost unrecognizable as portable computers, but they laid the groundwork for the devices that would follow.

The first mass-produced portable computer with a microprocessor was the Osborne 1, released in 1981. With a screen width of only five inches, it was heavy, bulky, and about the size of a sewing machine. But for the first time, a person’s computer and data could travel, even on commercial aircraft.

Throughout the 1980s and 1990s, other portable computers hit the market. The Compaq Portable was introduced in 1982, followed by the Tandy Model 100 in 1983. Commodore’s SX-64 was released in 1984. The Gavilan SC was first sold in 1984 and is noteworthy for being the first documented computer to be marketed as a “laptop.”

Other early laptops in the 1980s included the IBM PC Convertible and Hewlett-Packard Vectra Portable CS. Apple Computer introduced the Macintosh Portable in 1989, although 1984’s earlier transportable, the Apple IIc, had an optional liquid crystal display (LCD) screen. LCDs were much thinner than displays using cathode ray tube (CRT) technology.

It was the Apple PowerBook series of 1991 that is said to have pioneered the changes that became standard on laptops, such as a pointing device or trackball. The following year, IBM released its ThinkPad 700C featuring a similar design with a TrackPoint. Other laptop computers followed during the 1980s and 1990s, becoming lighter, thinner, and smaller with each incarnation until they too were considered prehistoric in the 21st-century age of the tablet and smartphone.

Nexus, Explorer, and Chrome

The 1990s brought a cascade of technological innovation to make the Internet accessible to average people. The Web browser, a way of navigating and retrieving information from the World Wide Web, was invented by the creator of the World Wide Web itself, Tim Berners-Lee. Browser software became more and more user-friendly through the 1990s, with versions evolving through the turn of the century with names including Nexus, Erwise, Mosaic, Netscape Navigator, Internet Explorer, Mozilla Firefox, Safari, and Chrome.

In 1993, electronic mail, or e-mail, took off with the speed of light. Though versions of e-mail could be traced back to the 1960s in the Cold War era, by 1997, the volume of business e-mail surpassed that of traditional postal mail.

The Web would light up in a dazzling array of images by 1994 made possible by the Joint Photographic Experts Group (JPEG). It now carried graphics, pictures, and photos. The next year, Microsoft introduced Windows 95, an operating system geared to “user-friendly” consumer operation.

The Internet search engine Google made its appearance in 1998. It became the most popular way to find needed information on the Internet, though it was not the first. Some earlier search products included WebCrawler and Lycos (1994), AltaVista, Excite, and Yahoo! (1995), and HotBot and Ask Jeeves (1996). It was the word “Google,” however, that would enter the language as shorthand, as in “to Google,” meaning to search for information online. The word “google” itself is a variation on the term “googol,” referring to the number 1 followed by 100 zeros, or a virtually infinite number.

The end of the post-Cold War era also brought about the technology to free Internet users from being tied to wiring. The year 1999 saw the emergence of Wi-Fi, the wireless networking technology that uses radio waves to provide high-speed Internet. Wi-Fi would become indispensable for those who wanted to shop online from a local coffee house upon the rise of e-commerce Web sites, which began being built in 1994. Companies offering e-commerce only, such as Amazon.com and eBay, quickly mushroomed.

Send in the Clones

Post-Cold War technology and innovation was not limited to computers. It found its way into genetics, outer space, and America’s dinner tables. In 1986, “Baby M,” the first child produced from a gestational surrogacy, was born, marking the first time in history that a child was born to someone other than the biological mother. Ten years later, in 1996, Dolly the sheep was cloned.

Looking skyward, the Hubble Space Telescope was launched in 1990. It revolutionized astronomy by allowing a deep view into space and time. That same year, construction began on the International Space Station. NASA’s *Pathfinder* landed on Mars in 1997, with a robot rover providing a close-up view of the Red Planet.

Post-Cold War technology landed squarely in American kitchens during 1994 with the introduction of the FlavrSavr tomato, the first genetically modified food sold in the United States.

“Must-Have” Technology

Consumer electronics really took off during the post-Cold War years. Many burned brightly as the hottest, most beloved “must-have” items on the market until they flamed out, usually being replaced by more advanced technology.

In 1980, the Sony Walkman was introduced to the United States, spurring a revolution in personal audio habits. After installing small batteries, listeners could play their favorite radio station or cassette tapes through lightweight earphones, adding an enjoyable

dimension to commuting, walking, working out, etc. In 1984, Sony introduced the portable Discman to play compact discs (CDs).

The beloved videocassette recorder (VCR) ruled the 1980s. People could record their favorite TV shows or watch movies whenever they wished. At the beginning of the 1980s, only a few people owned VCRs, with many waiting out the “format war” as Sony’s Betamax went head to head with VHS (Video Home System) from the JVC Corporation. Consumers fully understood that videotapes from one format would not be compatible with the other if the system they bought did not emerge victorious.

Due to costs, length of recording time, and other factors, VHS won that particular format war. However, Sony achieved payback with the success of its Blu-ray disc in the 2000s, by which time all VCRs were giving way to DVD technology.

Gordon Gekko’s Brick

The cellular telephone, or cell phone, was marketed to the public by Motorola in 1983. There were early versions of car phones and the “bag phone,” a plug-in mobile telephone device that came in a pouch. But it was the success of the 1987 movie *Wall Street* that helped cell phones turn the corner. Actor Michael Douglas as Gordon (“Greed, for lack of a better word, is good”) Gekko made a wireless call from the beach in chic Southampton, New York, catapulting the mobile phone into the spotlight as an 1980s icon. Gekko’s phone was the size of a brick, but it placed the cell phone firmly in the popular mind as synonymous with wealth, power, stylishness, and upward mobility, all deeply attractive to many in the 1980s.

Those who weren’t clawing their way to the top found other ways to pass the time in the post–Cold War years. In 1977, the video game console began filling the screens of American TVs in the form of *Donkey Kong* and *Pac-Man*. However, it was in 1985 that the Nintendo Entertainment System (NES) launched the Nintendo empire in America with such games as *Super Mario Bros.* Nintendo would be the forerunner of the Sony PlayStation avalanche of the 1990s and beyond.

It’s a Small World

The 1980s also saw a number of small digital devices become affordable, accessible, and desirable. The advancing technology of microprocessors combined steadily increasing performance with smaller size, allowing computer technology to find its way into everyday objects from cameras to calendars.

Digital cameras were commercially available by 1989 and generally replaced traditional photographic film by 2010. Personal digital assistants (PDAs) helped people keep track of their lives starting with the release of the Apple Newton in 1993. Later incarnations gradually merged their calendar features with cell phones.

The current incarnation of the automated teller machine (ATM) became commonplace in the United States during the 1980s, dispensing cash to eager Americans.

The field of home entertainment hit the big time in the post–Cold War years. Like full-color, flat-panel computer monitors, flat-screen TVs came to dominate the industry, sealing the demise of bulky cathode ray tube (CRT) screens and traditional television sets.

People also gained exciting new choices of programming to watch on their flat-screen TVs. In the 1980s, video stores allowed people to rent their favorite movies on videotape to watch at home. Those physical, “brick-and-mortar” shops would ultimately give way to video on demand via cable TV systems and video-by-mail services such as Netflix, which was launched in 1997, offering DVDs mailed directly to people’s homes. After the turn of the millennium, even those went the way of the dinosaur with the advent of computerized streaming, on-demand, and other services offering innumerable choices.

Smart Cars

The computers that came into flower during the post–Cold War years found their way into all manner of devices, including those that powered American transportation. From airlines to automobiles, computers took charge. Shade-tree mechanics began to find that their monkey wrenches were no match for tiny computer chips.

Automotive technology relieved the driver of a number of manual tasks like opening car windows, which were controlled by small motorized electronic mechanisms. Traditional car keys gave way to key fobs with embedded electronic chips. CD players replaced dashboard cassette decks. GPS navigation spared the driver from map reading.

TMI

During the 1980s and 1990s, the steady development of transmission technologies including computer networking, digital broadcasting, and the Internet brought previously unimaginable choices to Americans. To some people, the post–Cold War proliferation of technology and innovation hurt as much as it helped. Some cited negative effects of the digital revolution such as information overload, Internet predators, media saturation, social isolation, and a constant state of “buyer’s remorse” from having too many choices and too-rapid obsolescence.

The field of journalism was especially vulnerable as bloggers, tweeters, and other self-proclaimed “citizen journalists” with keyboards muddled the lines between personal opinion and documented reporting. Conspiracy theories multiplied, often with online sources simply reprinting verbiage from other Web sites, dubious or otherwise. With the advent of post–Cold War technology, both individuals and organizations suddenly had the ability to disseminate their views inexpensively on any topic to a global audience.

Thieves Rush In

One group especially rejoiced in the rise of post–Cold War technology for the public. They were the identity thieves who found they could “hack” their way into the Internet accounts of individuals and organizations. Criminals could steal personal and corporate information that allowed them to commit acts from applying for fraudulent loans using someone else’s credit cards to simply cleaning out people’s bank accounts. Accessing the computerized personal information of thousands of Americans, thieves could in turn sell the data on the black market.

The issue of privacy in general became a concern during the digital revolution of the 1980s and 1990s.

With huge amounts of all kinds of information being stored via computers and vulnerable to hacking, the activities and interests of private citizens could be tracked by computer monitoring and shadowy surveillance. Soon, people who assumed their e-mail messages were private often had a rude awakening.

Paperless Pipe Dream

Certainly, many people found the advantages of the post–Cold War digital revolution to outweigh the drawbacks. Experts predicted that American businesses would transform into “paperless offices,” work environments where the use of paper was greatly reduced or eliminated entirely.

By converting paperwork into digital form, proponents claimed that going paperless could save space and money and allow convenient sharing of documents, enhance productivity, keep personal information more secure, and help the environment.

Even at home, they argued, going paperless would mean the demise of such things as cookbooks and “hard-copy” recipes after homemakers converted their bulky, disorganized collections to computerized files.

However, as Greg Milliken wrote on WIRED.com in 2014, “When many organizations first began to transition from paper to electronic documents in the 1980’s, there was an initial reduction in the amount of physical paper used, but the truth is that we use more paper today than during the days of the Pet Rock.” Milliken cites statistics indicating that a billion photocopies are made each day and that the amount of paper generated by the average company grows by 25 percent each year.

The “paperless office” simply did not happen as predicted. Some of the reasons include the costs and productivity losses when converting to a paperless office. There was also the demand that all end users have the same hardware and software for reading documents as well as the same level of technological skills. Some skeptics also question the longevity of digital documents and system stability.

In addition, historians note that a large part of human history is known through written documents. Digital records can often be easily created but also easily modified or deleted altogether. And, changes in

storage formats can make data recovery difficult or impossible. Those with large amounts of information on floppy disks found out the hard way when floppies went the way of the eight-track tape.

Why 2K?

Another by-product of the post–Cold War years was the feared “millennium meltdown” or “Year 2000” problem, usually abbreviated simply as “Y2K.”

People—and especially the news media—took note of the issue in the late 1990s, as the turn of the century in 1999 would be followed by the new millennium. In the early days of the post–Cold War computer wave, storage was at a premium. In an effort by programmers to reduce usage, the date stored in many internal programs was formatted as six digits in the form of MMDDYY. “MM” was two digits for the month, “DD” was two digits for the day, and “YY” was two digits for the year. The prefix “19” for the year was felt to be understood; in other words, “July 1, 1985” was stored as “070185.”

It was speculated that some programs would not be able to distinguish between the year 2000 and the year 1900, with other programs trying to represent the year 2000 as 19100. There was fear of a complete system collapse, with results ranging from the inconvenient to the catastrophic as public utilities and critical infrastructure might fail. Some people cited nuclear power plants as a particular area of concern.

Businesses and governmental agencies sought to find all the areas that might be affected. In many cases, upgrading computer systems was assumed to be a solution. Still, it was hard to think of everything. Special committees were tasked with contingency planning if communications and crucial utilities were to fail. The Federal Emergency Management Agency (FEMA) looked to possible effects across the nation. While many felt the scare was overblown, most entities adopted a policy of “better safe than sorry.” Nothing could be certain until the calendar flipped to January 1, 2000.

Some organizations and agencies have since claimed that they sent out hundreds of press releases with research suggesting that the Y2K issue was not likely to be a problem. However, they were largely ignored by the news media in the face of meatier angles.

On January 18, 1999, a year before the supposed Y2K event, a leading national news magazine ran an eye-catching cover. A figure resembling a biblical prophet wore a sign saying, “The END of the World!?! Y2K insanity! Apocalypse Now! Will computers melt down? Will society? A guide to MILENNIUM MADNESS” (sic).

The inside story concluded that the necessary programs would be corrected in time, and the end of the world was unlikely. However, people seeing such a cover on newsstands without reading the article might be forgiven for assuming the worst. A Y2K-themed thriller feature film and made-for-TV movie were released. Wilderness survival boot camps became popular. Food and ammunition were stockpiled. Sources reported a spike in sales of SPAM canned meat.

When the clocks rolled over to January 1, 2000, there were no widely reported computer failures. Many looked back on the Y2K scare as a quaint piece of popular culture like radio’s *War of the Worlds* Martian mania in 1938. But many of those same people would not willingly have been flying in an airplane on December 31, 1999, at 11:59 p.m.

Orwellian World

With the rapid advances in computer technology during the post–Cold War era of the 1980s and 1990s, some people questioned the safety of storing vast amounts of personal data. Many forms of private information were being stored electronically at levels that were previously unseen. Some people feared not only identity theft but also the ability by the government and other entities to track individual activities and interests, such as which books they checked out of the library or which Web sites they visited. Advocates of privacy rights feared that by monitoring personal information, powerful centralized forces could control the population.

Some people had a term for the computerized world of the post–Cold War era: “Orwellian.” They were those who saw the 1980s and 1990s as actually the future envisioned by writer George Orwell. And it happened right on schedule: in 1984.

The book *Nineteen Eighty-Four* by English author Orwell was published in 1949. It is often called a

“dystopian” novel, depicting an unpleasant, dehumanized world controlled by a totalitarian state. There is constant government surveillance in *Nineteen Eighty-Four* along with manipulation of the public, persecution of individualism, rewriting of history, secret surveillance, and unending war. The government is controlled by the privileged elite of the Inner Party, which invented a language called Newspeak in which independent thinking is condemned as “thoughtcrime.”

In *Nineteen Eighty-Four*, the ruling party seeks power entirely for its own sake—just to *have* power instead of using it to help the people. The party leader is called Big Brother, who may not actually exist but attracts followers based on an intense cult of personality.

In Orwell’s dystopian world of the year 1984, the job of some workers is to rewrite past newspaper articles so that the historical record always supports the ruling party. In being instructed to forge and falsify documents, workers are told that they are correcting “misquotations.” Documents that cannot be altered are simply destroyed so no record exists of the government’s dishonesty.

Nineteen Eighty-Four meets 1984

In the actual calendar year 1984, there were numerous articles by contemporary writers who sought to determine how much of *Nineteen Eighty-Four* had actually come true. With the advent of e-mail, chat rooms, instant messaging (IM), and a later incarnation of messaging, texting, Newspeak’s truncated version of English became commonplace in the real world—“amirite?” The government-promulgated Newspeak in *Nineteen Eighty-Four* was rather more sinister, with such terms as “crimethink,” or ideas that were apart from the official government party line.

The new abbreviated language in the reality of the digital age was more geared to speed and convenience, such as BTW (“by the way”), B4N (“bye for now”), GR8 (“great”), IMHO (“in my humble opinion”), IRL (“in real life”), j/k (“just kidding”), L8R (“later”), and LOL (which could be either “laughing out loud” or “lots of love”). Much on the Internet today could be categorized as “DBEYR” (“don’t believe everything you read”).

A larger issue for many people in the post–Cold War computer age was the threat of the surveillance state as seen in *Nineteen Eighty-Four*. The concept of Big Brother was already being seen as a concern in the 1980s and 1990s, even before legislation after the terrorist attacks of September 11, 2001, made it easier for the government to conduct surveillance.

In the book *Nineteen Eighty-Four*, “telescreens” are dual-purpose devices, both playing televised propaganda and recording users’ activities. The two-way devices that became popular in the reality of the post–Cold War era were cell phones, which can be used to track and record their users.

Another feature of the book *Nineteen Eighty-Four* was providing the people, especially the poor, with a steady stream of diversions to fill their minds. Women were kept occupied with the care of home and children. Orwell wrote of the sports, entertainment, pornography, and gambling that were made easily available to the masses. Quarrels were promoted among different groups. The idea was to occupy the masses with distractions so they would not question the machinations of the government.

With the rise of actual computer-age arenas like Internet gambling, online pornography, and fantasy sports Web sites, some people felt that the real world of the 1980s and 1990s was Orwell’s fictional *Nineteen Eighty-Four* come to life.

With all its pluses and minuses (or *1s* and *0s* in digital form), such was the complex legacy of technology and innovation in the post–Cold War era.

AIDS Research

The history of the human immunodeficiency virus (HIV) and the illness it causes, acquired immune deficiency syndrome (AIDS), began in fear and death as the world faced a new, unknown pathogen. However, scientific advances, such as the discovery of the virus and how it is transmitted, the development of effective treatments, and new methods of prevention, have begun to limit the spread of the disease and enabled people with access to treatment to live longer and much healthier lives. When the U.S. Centers for Disease Control and Prevention (CDC) published information about early cases, it was the first official reporting about AIDS.

According to the Joint United Nations Programme on HIV/AIDS (UNAIDS), in 2015, there were 36.7 million people living with HIV; since the start of the epidemic, around 78 million have become infected.

It is widely believed that HIV originated in about 1920 in Kinshasa, in what is now the Democratic Republic of Congo, when HIV crossed species from

monkeys and apes to humans. The first verified case of HIV was found in a blood sample taken in 1959 from a man who lived in that region, which was retrospectively analyzed.

Up until the 1980s, it is not known how many people were infected with HIV or developed AIDS. The first cases were likely isolated ones among villagers who hunted and/or ate the meat of monkeys and apes. While sporadic cases of AIDS had been documented prior to 1970, available data suggests that the current epidemic started in the mid-to-late 1970s.

In 1981, five cases of a rare lung infection called *Pneumocystis carinii* pneumonia (PCP) were found in young gay men in Los Angeles. The CDC published information about these cases in its *Morbidity and Mortality Weekly Report* (MMWR).

Shortly thereafter, reports surfaced of young gay men in New York and California who had been diagnosed with a rare cancer called Kaposi’s sarcoma. This cancer forms from cells that line lymph or blood vessels and is caused by a virus. Both PCP and Kaposi’s sarcoma are usually found in people whose immune systems are suppressed. It was found that the men’s bodies were unable to fight these unusual infections. By the end of 1981, there were 270 reported cases of severe immune deficiency among gay men, and 121 of them had died.

Initially referred to as gay-related immune deficiency (GRID), in 1982, reports surfaced of cases in hemophiliacs and Haitians, indicating that the disease was spreading beyond American gay men. The same year, the CDC started to use the term “AIDS” to describe the illness.

In early 1983, the CDC suggested in another MMWR article that AIDS was caused by an infectious agent that was being transmitted sexually and/or through exposure to blood or blood products. U.S. health officials realized they had the makings of an epidemic on their hands, and Congress passed its first bill that included funds specifically for AIDS research and treatment.

A major outbreak of AIDS in Central Africa was then reported, signaling the beginning of the epidemic in other countries. The World Health Organization met in December 1983 to assess the global AIDS situation and start international surveillance.

The first scientific breakthrough in the cause of AIDS also came in 1983. Dr. Luc Montagnier and colleagues at the Pasteur Institute in France isolated a new retrovirus, which they initially called “lymphadenopathy associated virus” (LAV). Shortly thereafter, Dr. Robert Gallo of the National Cancer Institute also isolated it. Believing it to be related to a family of viruses called “human T-lymphotropic virus,” Gallo and his colleagues named it “HTLV-III” (it would be renamed HIV in May 1986).

This discovery was critical, for it enabled tests to be developed that could detect the presence of the virus in blood. It had been shown through the cases of HIV in hemophiliacs that the virus could be transmitted to others via blood transfusions, and there was great fear about contamination of the blood supply. At the time, in some U.S. cities, an estimated 1 in 90 transfusions was infected with HIV.

Researchers worked frantically on this problem. In March 1985, the U.S. Food and Drug Administration (USFDA) licensed the first commercial blood test for HIV, called the “enzyme-linked immunosorbent assay” (ELISA). It did not find the virus directly but was able to detect the antibodies made by an infected person’s body to fight it. This test enabled blood banks to start screening their supplies, and people at high risk for contracting the disease could be tested as well.

Unfortunately, the discovery of the virus also showed that it had properties that make it very difficult to develop a conventional vaccine against. This made it crucial to find effective medications to fight it. The U.S. government and health research agencies poured money into the project. In October 1985, Congress allocated nearly \$190 million for AIDS research, almost 16 times the amount allotted in 1983.

In March 1987, the FDA approved the first drug treatment for HIV: zidovudine (AZT). AZT works by preventing the virus from multiplying. It was approved in record time with only one trial on humans instead of the standard three. That trial was stopped after only 19 weeks, because the group of control patients in the study who were not receiving the drug were dying faster than the ones who were. At the same time, the FDA issued new regulations to fast-track experimental HIV medications, accelerating drug approval by two to three years.

The early and mid-1990s would see the development of HIV tests that doctors could use in their offices, would show results in as little as 20 minutes, and that could use saliva or urine instead of blood. These simpler, rapid tests would prove to be valuable tools in countries where expensive and time-consuming tests were difficult to perform.

In June 1995, the FDA approved saquinavir, another drug that prevents the virus from replicating, but in a different way than AZT. This and subsequent approval of other drugs ushered in a new treatment regimen for AIDS called “highly active antiretroviral therapy” (HAART), which uses a combination of several medications that inhibit the virus in different ways. HAART brought about an immediate decline in rates of AIDS-related deaths and hospitalizations. While none of the drugs are a cure, they can hold the virus in check for prolonged periods if taken regularly.

In 1996, the Joint United Nations Programme on AIDS (UNAIDS) was established to advocate for global action on the epidemic and coordinate the response to HIV/AIDS among United Nations countries. UNAIDS was instrumental in negotiating with five pharmaceutical companies to reduce antiretroviral drug prices for developing countries, another critical piece of fighting the worldwide epidemic.

As older HIV medicines began to lose their patents, generic drug manufacturers began producing much cheaper versions for developing countries, causing several major pharmaceutical manufacturers to agree to further reductions in drug prices. In November 2001, the World Trade Organization (WTO) announced the Doha Declaration, which allowed developing countries to manufacture drugs to combat public health crises like HIV even if they still had patents.

In the early and mid-2000s, studies confirmed that medications could also be used as a means of preventing HIV transmission to people who were HIV-negative but at high risk of contracting the disease through sexual activity. These medication regimens, known as “pre-exposure prophylaxis,” or PrEP, include both oral medications and novel methods of delivery, such as the dapivirine vaginal ring designed to be a low-cost and discreet method of prevention for women in developing countries.

The years 2012 and 2013 marked turning points in the fight against AIDS, as UNAIDS reported that for the first time, the majority of people eligible for HIV treatment (54 percent) were receiving it. Additionally, new HIV infections had dropped more than 50 percent in 25 low- and middle-income countries, and AIDS-related deaths had fallen 30 percent since their highest point in 2005.

In September 2014, UNAIDS called for a massive and ambitious scaling up of HIV prevention and treatment programs to prevent new infections and end the epidemic as a public health issue by 2030. By 2016, UNAIDS announced that 18.2 million people were on drug therapy, including almost a million children, double the number five years earlier.

However, UNAIDS reports also noted an emerging problem with HIV mutations, which are resistant to first-line drug therapies partly as a result of patients not taking their medication regularly. This points to the importance of ensuring that people stay on

treatment and to the need for a vaccine or cure for HIV. In November 2016, the National Institutes of Health announced a large-scale vaccine trial in South Africa, which, if successful, may signal the next important breakthrough in AIDS research.

Primary Document: Introduction to the AIDS Archive by Former Surgeon General C. Everett Koop

In this Introduction to AIDS Archive, which resides on the Profiles in Science Web site of the U.S. National Library of Medicine, former surgeon general C. Everett Koop explains how and why he began educating the American public about the disease. Acquired immune deficiency syndrome, a disease involving a severe loss of the body's cellular immunity that lowers the resistance to infection, first appeared in the United States in 1981, a year before Koop took his position in President Ronald Reagan's administration.

AIDS entered the consciousness of the Public Health Service quietly, gradually, and without fanfare. I was at a staff meeting in June of 1981, as the Surgeon General designate, when the Centers for Disease Control published a report and discussed it at a staff meeting concerning five “previously healthy homosexuals,” who had been admitted to Los Angeles hospitals with pneumonia caused by a very rare organism—pneumocystis carinii.

By the time the report was published, two of the men had died. The other three died shortly thereafter. Five cases are certainly not many, but this lethal pneumonia was so rare that a handful of cases in a single year—especially in a single place—constituted an epidemic. Soon reports trickled in of cases in other cities.

Then a month later, the Public Health Service published a report that 26 young homosexual men had been recently diagnosed as having Kaposi's sarcoma, an “uncommonly reported” cancerous condition, usually found, if at all, among elderly men.

I was the only one at the staff meetings who had ever seen pneumocystis carinii pneumonia, and that was because I worked in a children's hospital where I did lung biopsies to make that diagnosis in children who were immuno suppressed because of cancer chemotherapy. I had also seen one case of Kaposi's sarcoma in my entire life, and that at the Allgemeine Krankenhaus in Vienna. From that small beginning, the AIDS epidemic of the late 80s mushroomed.

Epidemiologists from Centers for Disease Control opined that these otherwise healthy normal people were apparently acquiring some type of virus that attacked and destroyed their immune system. The virus itself was not killing these people, they were succumbing to other extremely virulent diseases—eventually called “opportunistic diseases,” because this infectious agent, whatever it was, prevented the body from fighting them off. Since the first cases affected only homosexuals, the Public Health Service called the disease, “GRID”—Gay Related Immune Deficiency. Shortly thereafter, as heterosexuals began to fall victim to it, GRID became the “Acquired Immuno Deficiency Syndrome,” or A.I.D.S., which was shortened to just AIDS. Although, I was in on AIDS from the start, I didn’t assume an important role in government in reference to AIDS until the end of Ronald Reagan’s first term in office. By August 1981, I and others, who were paying attention to the unusual news from the CDC, learned that there were 108 cases of AIDS reported with 43 dead. I knew then that we were in big trouble. My first real confrontation with other members of the Public Health Service came when I said, “If this is a homosexual disease, one of the things we will have to come to grips with, early on, if we are to control it, is the forced sodomy which takes place in prisons and would be a source of rapid spread of the disease.” No one at the staff meeting agreed with me, and it was years before anyone, especially the Centers for Disease Control were talking about AIDS among prisoners.

I realize that if ever there was a disease made for a Surgeon General, it was AIDS. The Surgeon General is mandated by Congress to inform the American people about the prevention of disease and the promotion of health. If ever there was a public in need of education and straight talk about AIDS, it was the American people.

But for an astonishing five and a half years, I was completely cut off from AIDS. The Assistant Secretary for Health, my immediate boss, told me that I would not be assigned to cover AIDS. The Department took its cue from him. Even though the Centers for Disease Control commissioned the first AIDS Task Force as early as June 1981, I as Surgeon General was not allowed to speak about AIDS publicly until I took it upon myself to do so.

Whenever a two-term President is awaiting his second inauguration, and lame-duck congressmen and senators are packing boxes to move on, presidential appointees begin to leave Washington like rats leave a sinking ship. One of the things I realized early on about political appointments was that many accepted them in order to become expert in some phase of government operation so that they would be able to convert that expertise into big bucks. Indeed, a lot of them spent the President’s first term standing on tiptoe looking into the distance for that six-figure job.

As people in the Public Health Service, who had appointments by President Reagan began to go home, there was no one left to police me, and in as much as I felt better able to communicate with the public than anyone who was left, and really not understanding why I had been so confined, I began to attend meetings, ferret out information, and it remained for President Reagan to give me an assignment that catapulted me into the position of chief spokesperson for the government in reference to AIDS. When I say chief spokesperson that meant to the public, to the Congress, to the health departments of foreign governments, and to the United Nations itself.

It happened his way:

The day after President Reagan gave his “State of the Union” message after inauguration in 1987, he, in an unusual move, came across town to the Humphrey Building and in the great hall spoke to a packed house, standing in the atrium, about his gratitude to them for the way they were handling the health problems of the nation of which AIDS was one. Toward the end of his speech he said, “I’m asking the Surgeon General to prepare a report on Acquired Immuno Deficiency Syndrome for the people of the United States.” It’s good that I was listening carefully, because that’s the only directive I had from anyone about that report. I proceeded with an appropriate degree of urgency, selected a few close associates to be my staff for preparation of this document and then set about informing various segments of the public about what I felt I had to say about AIDS in the report, and learning from them which points were supersensitive, and would require discussion to me before the various organizations would accept what I felt essential to say to the public.

This story would not be complete if I didn't mention the fact that the Reagan revolution brought into positions of power and influence Americans whose politics and personal beliefs predisposed them to antipathy toward the homosexual community. This influenced the AIDS crisis in two ways. First, it slowed the understanding of AIDS. In the early years of AIDS, (also the early years of the Reagan Administration), health officials were shocked and dismayed by the link between the spread of AIDS and the promiscuity and perversity of many homosexuals' behavior. Revelations about the promiscuity of some homosexuals with multiple partners and the fact that sodomy with multiple anonymous partners provided valuable information about a possible method of AIDS transmission: semen of one to blood of the other, led to a profound reluctance on the part of some health officials to discuss these sensitive (some said abhorrent) issues publicly. So, under directions from more than one White House source, they simply made vague references to "exchanging bodily fluids" thus, considerably slowing down the public's understanding of how AIDS can be transmitted.

Second, the conservative politics of the middle and late years of the Reagan Administration attempted to thwart my attempts to educate the public about AIDS and tried to stir up hostility toward its victims. I tried to rise above the politics of AIDS, but it would cost me many friendships. Just to keep you informed about what was happening in science elsewhere, in May 1983, Robert Gallo of the National Institutes of Health and Luc Montagnier of the Pasteur Institute in Paris, identified the infectious agent that caused AIDS: A virus dubbed HIV-III or Human Immuno Deficiency Virus. In early 1984, there were over 5,000 reported cases of AIDS with 2,300 deaths. In spite of all that I've said there was no public outcry or any outcry even from organized medicine for more and appropriate leadership from the government. In 1985, as the Public Health Service and other branches of the medical community learned more about AIDS, they provided a weapon in this struggle against this strange disease: a test to identify the presence of antibodies to the HIV virus in the blood supply.

In spite of the confusion, frustration, anger, and ignorance, the government did press forward and make astounding advances in medical science

and research. We learned as much about AIDS in six years, as we had learned about polio in forty. It was a testament to these unflagging efforts that a reliable blood test was discovered and made generally available as early as the fall of 1985.

That test changed a lot. The odds of getting an AIDS contaminated unit of transfused blood fell from between 1 in 40 thousand, to 1 in 250,000. Compare those odds with say, death on the highway 1 in 5,900.

Dr. Tony Fauci, later to direct AIDS research at the National Institutes of Health, insisted we check out any study that did seem to rule out the spread of AIDS by casual contact. Gradually, a convincing body of research led us to some important conclusions, because of that we stressed four important conclusions about AIDS:

It was fatal
It was spreading
It was transmitted mainly by certain specific
behavior involving sex and/or drugs
There was no cure.

Ed Brandt, the Assistant Secretary for Health, had left the administration to go to the University of Maryland as Provost on the Baltimore campus and had been succeeded by James O. Mason as Acting Assistant Secretary for Health. Mason made me a member of the AIDS Task Force. He and I also agreed that AIDS demanded a clear spokesperson, and I could make any statement I thought appropriate. At last, I could speak up.

Meanwhile, I was preparing the report the President had requested, and I met with 27 distinct groups representing AIDS advocacy, business, education, health, labor, public officials, and religion . . .

Without representatives from the aforementioned groups, there would have been no AIDS report. I needed to be in touch with all of the national groups that were concerned about AIDS. I wanted to make sure they knew what I was doing, and I wanted none to say, after the report was published that they had been blindsided or kept in the dark.

Maintaining control of the report, keeping the circle small, meant that I would have only a very small staff to help me. Dr. Michael Samuels brought with him a broad background of public health endeavors, and he also brought the part-time help of Jim McTigue, a commissioned officer with whom Mike

and I had frequently worked on intergovernmental affairs. We were supported by a small team: the Assistant Surgeon General, Jim Dixon; and Edward Martin, my Chief of Staff; my Deputy Director of the Office of International Health, Hal Thompson; my personal assistant, Stephanie Stein; and of course, my Deputy Surgeon General, Faye Abdelluh.

The information provided by the National Hemophilia Foundation was critical. We had more information on hemophiliacs and their behavior while infected with HIV, than we had on any other group. Their infection, of course, had come from contaminated blood and blood products used in the treatment of their disease.

I found the people from the Southern Baptist Convention to be delightful, but very naive about AIDS. I think they were shocked by what we had to tell them, about how the virus was sexually transmitted. I thought they might be uncomfortable with a mandate for sex education I planned to mention in my report, so I challenged them to write their own sex education curriculum for their twenty-six million constituents. To their credit, within six months of our chat, they did what I had suggested, and I had the pleasure of giving their annual convention's keynote address when they announced their curriculum on human sexuality.

I released the report on Acquired Immuno Deficiency Syndrome that the President had asked me to write, on October 22, 1985. It is amazing that this was five years and four months from the first internal discussion of AIDS by the Public Health Service in the Humphrey Building on Independence Avenue, in June of 1981.

There is a story about my presentation of the report to the Cabinet that appears no place else that I know of, except in my autobiography. We had ordered a huge supply of this document on the cheap stock that the government usually uses for such reports. My concern was that when I presented the report, some members of the Cabinet would ask that changes be made too "soften" the language. Inasmuch as I felt that specific language was essential to my mission, I devised a plan to present each of the Cabinet, not with a cheap paper report, but one on glossy paper, bound with a cover in royal blue (the Public Health Service color), and imprinted with the title and the great seal of the Public Health Service in silver. My

hope was that they would assume the report was so expensive that they would not suggest that the thousands upon thousands that had already been printed be scrapped, in order to make a few words changes. I was right, and no changes were made. The report was presented to the public by way of a press conference the following morning, October 22, 1985. A copy of the report follows, which will lend credence to the lectures that follow.

In the lectures that follow, there will be a sampling of the talks I gave on AIDS beginning with January 15, 1987 and progressing on for the next several years. Because, in this archive, all the AIDS speeches will be together, each introductory page for each individual lecture will only cover matters pertinent to that lecture, which have not been covered in previous introductory material. The reader will also know how much time elapsed since the last report by lecture to the public, and in that way, the reader will understand that lectures are given in close sequence, not much increase of knowledge. However my presentation changes depending upon the venue, the audience, and the past history of that audience in reference to AIDS.

The report that was given by me in 1985 to the American public still stands pretty much today as truth. The exceptions are these: we now know that all people are not equally susceptible to infection by the virus, but we can measure who they are, and the treatment has been refined greatly. In many of the early lectures I mention treatment with AZT, (Zidovudine, formerly Azidothymidine), which I said, merely prolonged life. We now know that that's all any treatment can do, because thus far, AIDS is not curable, and we are still without a vaccine. However, with proper treatment, started early, it is possible, probably to live out one's normal life expectancy and die of other causes.

In any lecture, especially by a government officer, it is the question and answer time that is more important. It is the most stressful and demands the greater depth of knowledge.

The report was written for American consumption, although it was used by a number of foreign countries when it was published, either in whole or in part, and was the template that served in the writing of the British report to its own people.

This introductory writing is being undertaken in the winter of 2002–2003, when the world faces

genocide from AIDS in some of the countries of Africa and Asia. In these countries, poverty, sexual custom, lack of databases, denial, illiteracy and poor health education, as well as faulty government policy contribute to the terrible scourge that AIDS has

become in the developing nations. Money can't fix it all, but it would go a long way to help.

Apple

Apple Inc., is an American technology company that designs, develops, and sells consumer electronics, computer software, and online services. With \$1,300, Steve Jobs (1955–2011) and Steve Wozniak (1950–) founded Apple in 1976. Although both men were knowledgeable in electronics and possessed the ability to innovate, Jobs's major strength was his gift for envisioning future technological possibilities, while Wozniak excelled in making some of those dreams a reality. After years of vision, hard work, and ingenuity, a business begun in a garage grew to be one of the world's largest technological corporations.

Early on, Apple's main competitor was International Business Machines (IBM), a major seller of various types of machines for the office. In the 1970s, the personal computer (PC) for the home was almost universally considered a high-tech toy. In like manner, people who bought PCs were usually seeking to engage in a technology-related hobby. The duo built and sold 250 Apple I (hobby machines) out of Jobs's garage for \$666 each. However, Jobs had a much grander vision for Apple PCs. If Apple could find a way to integrate PCs into people's daily lives, he believed, PC technology would become indispensable at work and at home. Consequently, Apple engaged in a marketing campaign that showcased the educational value of PCs for young children. Apple also developed computer software to promote problem-solving skills and creativity. Many schools and parents purchased PCs for their children. In fact, many educational leaders rewrote state K-12 curriculum standards to reflect a need for the use of technology in the classroom.

Apple's strategy of marketing the PC as an educational boost for young children had two major benefits. First, it led to the sale of millions of PCs. Second,

by assimilating the young to computers, Apple secured a future computer-literate consumer base. Sales could also be generated with continual innovation. As new computers with more advanced hardware and software rolled off the factory floor, older computers and older software would become obsolete. If innovations were significant enough, consumers would keep upgrading.

With Apple II and Apple III, profits were so great that in 1980 (just four years after the company's establishment), it was converted to public ownership. Although Jobs and Wozniak gave up ownership of Apple by going public, they enjoyed great monetary rewards. The new Apple chairman, Mike Markkula, hired Mike Scott as president. Jobs functioned as a consultant and Wozniak as an engineer. Scott left Apple after one year. Consequently, Markkula assumed the presidency, and he promoted Jobs to chairman.

In 1982, Apple became the first PC company to reach \$1 billion in annual sales. In 1983, Apple challenged IBM with the Lisa, a new business machine. Jobs hoped to gain an edge in the business market with Lisa's more user-friendly mouse, pointer, and computer screen, but Apple was unable to break IBM's hold on the business market. Due to low Lisa sales, Apple's stocks fell to half their value. In spite of the failure, Jobs pressed on with the Macintosh ("the people's computer"), which made use of all of Lisa's innovations but was sold at a fraction of Lisa's cost.

Jobs believed that Macintosh's ease of use and two-disk memory drive gave it a tremendous advantage over all other PCs on the market. In fact, he was convinced that anyone who tried it would buy it. Macintosh sold very well the first year, but sales faltered after that. In 1985, John Sculley assumed the

presidency after a management shakeup that caused the departure of Jobs and several other Apple executives.

During the 1990s, Sculley expanded Apple from a school and home PC maker to a business computer company. In addition, Apple's focus was on providing consumers with more powerful machines, including the PowerBook (1991). However, low profits led to Sculley's dismissal in 1993. President Michael Spindler generated quick short-term profits by licensing Apple technology to outside firms. Unfortunately for Apple, this resulted in a market flooded with Apple clones, which dramatically drained Apple's long-term profits.

According to analysts, during these years, Apple's bad fortune was more closely tied to mismanagement than a lack of technological innovation. For example, Power Macintosh (Power Mac) computers, which were released in 1994, were highly sought after. However, executives grossly underestimated the demand for the product, and by 1995, Apple had \$1 billion of orders it could not fill. By 1997, the company's stock was trading at only \$14 per share (compared to \$70 per share in 1991).

In 1996, Apple acquired NeXT (Steve Jobs's company) for \$377 million. As part of the negotiations, Jobs agreed to return to Apple as a special advisor. In 1997, Jobs was named interim chief executive officer. He regretted that Apple computers and related computer software had fallen out of favor with the public. In 1998, he unveiled the iMac, an all-in-one, colorful computer that showed off Apple's skill with design and functionality. Although sales spikes were modest compared to the company's prior glory days, Apple's profits steadily improved. In fact, by the end of 1999, Apple's stocks sold for \$99 per share. By 2000, Jobs was firmly in command as chief executive officer (CEO). In the 2000s, Apple saw even greater growth with the sale of smaller and more personal devices.

In 1979, the Sony Corporation had unveiled the Walkman TPS-L2, a portable cassette tape player with headphones, which became one of the most popular consumer items of the 1980s. Jobs dreamed of a less bulky digital device to rival the Walkman, and he challenged Wozniak to develop it. But, even by the 1990s,

the technology to produce a quality product of this type did not exist. It was not until 2001, when Toshiba unveiled a 1.8-inch hard drive, that developers were able to realize Jobs's vision. In 2001, Apple released the iPod, a digital music player with five gigabytes (GB), which allowed for the storage of about 1,000 songs.

The next year, Apple released a 10 GB model. Then, iPods were released in assorted sizes and colors. In 2005, Apple released a video iPod, the fifth generation of the device. By that year, total iPod unit sales had reached 30 million, and iTunes (Apple's online digital download store) sold music, videos, and audiobooks.

In 2007, Jobs unveiled the first iPhone (a touch screen-controlled mobile phone with Internet capabilities). In the first 200 days after its release, Apple sold 4 million iPhones. By 2009, 30 million iPhones had been sold worldwide. Usually, each succeeding generation of iPhone featured some sort of improvement (including a faster 3G network connection speed, a wider screen, and more useful applications). Jobs unveiled the iPad, a portable computer tablet, in 2010, and iCloud (storage and synchronization of digital content across computers, iPhones, iPads, and iPod Touches) in 2011.

By the 2000s, some of the products that Apple produced, including smartphones and computer tablets, had caught up technologically to gadgets previously only imagined by science fiction writers. Apple had become one of the biggest corporations in the world. Like other corporate giants, Apple had its share of controversy. For example, like several other major U.S. companies, Apple had most of its products assembled in China, where low wages and dangerous working conditions were the norm. In China, managers placed enormous time pressure on employees. In one factory, suicide attempts were so high one year that factory managers placed safety nets around the buildings to try to prevent jumpers from dying.

In 2011, 64,000 Silicon Valley workers filed a class action suit against Apple and other technology companies, charging that they had agreed not to recruit each other's employees. Also, some Apple executives resigned after they were accused of illegally backdating stock (buying Apple stocks at past, lower prices).

Since 2012, Apple CEO Tim Cook was embroiled in a congressional investigation concerning charges of Apple’s tax evasion.

In spite of these and other problems, for the most part, the general public remained loyal to Apple. The public loved Apple products, which had become status symbols. Some people stood in line for days to buy the newest iPhone. Most of all, the public had come to trust Jobs’s talent for technological innovation. Even though Apple sales were strong in 2011, stocks fell immediately after Jobs’s death from cancer, because many people wondered just how innovative Apple would be without him. Apple’s story illustrates how innovation is only possible when the right vision converges with the right type of technology.

Apple II

In the 1970s, the personal computer was introduced to the home market. Prior to the 1970s, computers were advertised mostly to businesses. The Apple II is considered to be Apple Computer’s first successful computer, and it created the company’s philosophy of simplicity. Today, Apple is known as a worldwide

Apple Computers cofounder Steve Jobs poses with the Apple II computer, 1979. Jobs and associate Steve Wozniak helped launch the computer revolution, which grew into the cell phone revolution within 20 years. (Ralph Morse/Time Life Pictures/Getty Images)

technology brand. Many people credit the Apple II for elevating Apple as one of the top tech companies globally.

During the 1970s, there were only two other major computer products, Commodore’s PET 2001 and Radio Shack’s TRS-80, in the personal computer market. Established in 1976, the Apple Computer company, formed by Steve Wozniak and Steve Jobs, focused on the home market and introduced the Apple II at the West Coast Computer Faire, a tech event hosted in San Francisco, California.

Like its competitors, the Apple II was one of the first computers with a color display. It also came with a built-in BASIC programming language. To make

things even more user-friendly, it was ready to run as soon as it was turned on. The Apple II is referred to as the first user-friendly computer system. The insides of the Apple II were essentially designed by Wozniak. Jobs is often praised for his contribution in the aesthetics of the Apple II (and all future technology that came from the company, including the iPod, iPhone, and iPad).

One thing that separated the Apple II from its competitors was its eight expansion slots. No other computer had yet to offer this feature or option. The top of the computer was also detachable, which made modifying the hardware much easier for the skilled computer aficionado. In 1979, Daniel Fylstra, a computer programmer, created VisiCalc, a computer application for the Apple II. This application was used to do business calculations and to forecast finance. This application made the personal computer a tool for people who did not know how to create applications. VisiCalc's success correlated with the Apple II's unit sales.

The Apple II's price was \$1295, and it sold 35,000 units in its first fiscal year. The company would continue to flourish throughout the years. Apple ultimately became the first personal computer company to reach \$1 billion annual sales in 1982. The Apple II revolutionized the target audience for computer companies. They no longer focused solely on business customers; the market expanded to every single person.

Today, the Apple II is no longer manufactured due to various innovations created by Apple, but it was the cornerstone for the success and philosophy of the company. Many of today's Apple products continue to take the "simplicity" approach pioneered by the Apple II.

Artificial Heart

An artificial heart is a mechanical device designed to replace a human heart. A reliable synthetic heart is considered the "holy grail" of medical science. In 1982, a team of doctors implanted a Jarvik-7 artificial heart into Barney Clark, who then lived for 112 days. This is considered the first successful artificial heart transplant. Today, artificial hearts are generally considered for patients unsuitable for human heart transplants. The ventricular assist device (VAD) operates similarly to the artificial heart but is not meant as a heart replacement. VADs are now commonly used in cardiac surgeries.

Russian Vladimir Demikhov transplanted a mechanical heart into a dog in 1937. Demikhov later became famous for his dog head transplants, which resulted in two-headed dogs. In 1949, William Sewell and William Glenn successfully applied a bypass procedure to a dog's heart, and in 1957, Willem Kolff performed an artificial heart transplant on a dog, though the dog only lived 90 minutes after the surgery. Kolff became one of the most prolific artificial heart transplant scientists of the 1960s and 1970s. He had some success implanting artificial hearts into cows in the 1970s using hearts of his design and then using Robert Jarvik hearts. The National Institutes of Health established an artificial heart program in 1964 that aimed to successfully implant an artificial heart into a human within 10 years.

In the 1970s and early 1980s, Robert Jarvik designed a number of artificial hearts with his mentor, Willem Kolff. The Jarvik-7 was, like previous artificial heart models, a self-contained, pneumatic mechanism. The heart's control mechanism, which was as large as a small household stove, was attached to the heart with pneumatic tubes that ran through holes in the patient's chest. Thus, while better than previous heart designs, the Jarvik-7 limited patient mobility and carried a high infection risk.

Artificial heart models in the 1980s continued to rely on large, exterior pumping mechanisms and

power sources. By the 1990s, researchers had begun developing smaller artificial hearts. In 2001 a two-pound, rechargeable-internal-battery-operated heart called the AbioCor was successfully implanted. Though smaller than earlier hearts, the AbioCor is too large to be used on anyone but larger men. It has a lifespan of one to two years and is considered suitable only for critically ill patients ineligible for human heart transplants.

In 2011, a Frazier-Cohn heart, which had been successfully transplanted into sheep, was transplanted into Craig Lewis at the Texas Heart Institute. The heart extended Lewis's life for 5 weeks before he succumbed to liver and kidney failure. Artificial heart researchers are currently working on a soft artificial heart made from silicon with a 3-D printer. The heart is meant to look and function like a real human heart. In 2017, research was still preliminary.

Ventricular assist devices, or VADs, are related to but different from artificial hearts. VADs are not meant to replace hearts but to assist failing hearts. Argentine American Domingo Liotta invented the first VAD and is thus considered one of the great innovators in cardiac surgery and cardiac prostheses, including artificial hearts.

Critics point out that there has never been a truly successful artificial heart despite decades of research and millions of dollars of investment. Rather, artificial hearts are emblematic of medical research that regards all human body parts as replaceable while ignoring the human suffering caused by research and testing.

Artificial Intelligence (AI)

A modern definition of artificial intelligence (AI) is intelligence exhibited by a machine, created using a

combination of approaches and software tools, to implement an intelligent agent that can store and use knowledge obtained through perception, deduction, and reasoning to implement problem solving, planning, and learning that may control the movement of people and the manipulation of objects. Early efforts in creating AI centered on one approach or software tool but were found to be of limited usefulness. Modern AI systems are composed of a combination of approaches and software tools and more closely resemble what humans would view as intelligent.

The general problem in creating AI can be broken down into several subproblems:

1. Deduction, reasoning, and problem solving
2. Knowledge representation
3. Planning
4. Learning
5. Natural language processing
6. Perception
7. Motion and manipulation

Due to the complexity of the problems in AI creation, there have been many different approaches, with varying degrees of success. For instance, a logic approach is not easily applied to the perception problem domain. This has been somewhat rectified by combining approaches. However, some of this disappointment is due to the problem of the AI effect: after a technique is perfected, observers no longer consider it to be true artificial intelligence. Even a computer that can beat a chess champion is viewed as only performing calculations.

The following is a list of some of the approaches to AI:

- *Cybernetics and Brain Simulation.* One of the early approaches to AI was an attempt to simulate the action of neurons that control and use information to then control systems. The approaches known as “computational neuroscience” and “cybernetics” were largely abandoned by the 1950s. However, more recently, with the advent of more computing resources, neural networks have seen success in computer vision and speech recognition through deep learning systems.

- *Symbolic.* Symbolic AI became the focus of most researchers in the 1950s. Allen Newell and Herbert Simon thought that general, intelligent action could be realized using symbols and their associated processes, which are described using expressions. This line of thought resulted in an attempt to produce systems using different symbols, processes, and expressions. Cognitive simulation was used to describe the processes and expressions that the human mind uses to give meaning to symbols. Some used logic to describe the processes and expressions, which resulted in the Prolog programming language. Some rejected the use of generalized processes and expressions, creating a custom process for each solution.
- *Subsymbolic.* By the 1980s, it had become obvious that symbolic AI was not producing useful AI. Researchers began to imagine systems where there was no specific representation of knowledge. Rather, machines should be able to discover knowledge. The discovery of knowledge can be made by evaluating a large number of generated solutions and choosing the best one. For instance, genetic programming seeks to define a random initial set of individual solutions, which are associated with a metric for rating their success in solving the problem. Subsequent generations are created by selecting the best individuals from the current generation and then making some random changes to their solution. This process is continued for a number of generations before the best result is selected as the final solution.

Fuzzy logic systems function by first categorizing inputs into concepts (linguistic classifications) and then performing calculations on the concepts and evaluating the result. Fuzzy logic systems are often used as control systems. Recently a fuzzy logic system called ALPHA has been tested for controlling unmanned combat aerial vehicles and has been found to be extremely effective.

The high number of inputs and outputs to be considered by ALPHA was handled by a new AI tool: the genetic fuzzy tree (GFT). The GFT solves the problem of a large number of variables by creating a collection of fuzzy inference systems (FISs) that can run in

parallel. The FISs classify the inputs and outputs into a linguistic classification, which reduces the runtime work and allows for easy programming of the system by knowledge experts.

ALPHA is a genetic fuzzy system where a genetic algorithm creates all of the components of the controller multiple times. Each automatically generated version of ALPHA competes against a manually tuned version of ALPHA to determine if it is better. Eventually, one version of ALPHA is chosen as the best. This method has seen success in the realm of AI.

In the 1990s, the use of statistics and sophisticated mathematical tools became important in the discovery of solutions to problems. Many problems in reasoning, planning, learning, perception, and robotics have incomplete or uncertain information. Mathematical tools like probability theory and economics help to solve these problems. Statistics help a deep-learning neural network classify objects and recognize words.

The varied approaches to AI have been used alone or in combination in ways that have been identified as general AI tools used to solve problems. These classes of tools may be used to solve different problems. Some of the problems and the class of tools used to solve them are listed in the following table.

Problem	Tool
Find the best solution	Search and Optimization
Control systems	Genetic Fuzzy Tree
Represent knowledge and solve problems. Learning.	Logic Programming, Prolog
Solve problems with limited information	Probabilistic Algorithms
Learn with limited information	Statistical Learning
Computer vision, speech recognition, natural language processing	Deep Learning Neural Networks

For individual tools, one may combine different approaches to create the best AI tool. For example, neural networks and genetic programming can be

combined to produce the best tool. Under this scenario, several neural networks with number of nodes, weights, and connections are the initial individuals that are subsequently evaluated, selected, and modified for future generations. After several generations, a particular neural network is identified as the best according to the associated metric (for instance, how well the neural network is able to identify objects). In other implementations, one could use logic programming on fuzzy logic facts or use a sophisticated mathematical tool to define a genetic programming metric.

The implementation of AI at the system level usually relies on a combination of approaches and tools. While one approach or tool may solve a specific problem (like providing a control system to an unmanned aerial vehicle), systems usually solve several problems simultaneously. Many combinations of neural, symbolic, subsymbolic, and mathematical approaches and tools may be needed when designing and implementing an AI system.

For systems, researchers find that they may need to combine several AI tools. For instance, an unmanned aerial vehicle needs AI to control the aircraft using a genetic fuzzy tree, but it also needs to understand its surroundings through computerized vision tools implemented using deep learning neural networks. One can imagine that probabilistic and statistical learning algorithms could be helpful in the competitive and unpredictable environment of a battle.

AI systems are composed using AI approaches and AI tools; however, due to the AI effect, many of the systems are not viewed as true artificial intelligence systems. The AI effect has been described as occurring when an AI tool or system becomes commonplace. The result of the effect is that observers may complain that the system is only performing simple calculations and is not a “true” AI.

The number of application domains where AI is being used is growing rapidly. Some success stories for AI have been found in the following:

- Fraud protection systems to counter the unauthorized use of credit cards
- Natural language processing for online and telephone automated assistance

- Computer-assisted interpretation of medical and satellite images
- Toy robots and video games
- Autonomous airplanes and cars
- Industrial robots
- Computer-generated news and reports
- E-mail spam filtering
- Investment decisions

The following ethical concerns surround artificial intelligence:

1. Are intelligent machines dangerous?
2. Can intelligent machines have a consciousness in the same way that a human does and therefore deserve certain rights?
3. Can or should machines be programmed to make ethical decisions? How does a biased human programmer affect the bias of the machine?
4. Should intelligent machines reduce or eliminate human jobs?

While most discussions of ethics may be premature given the limited abilities of intelligent machines, there are many people and groups talking about how to keep AI ethical. Bill Gates, Stephen Hawking, and Elon Musk have all voiced concerns about the potential threats from AI. As scientists and engineers develop more and more artificially intelligent machines, they will increasingly integrate into human lives. Ethical concerns should only become more important as AI becomes even more common and increases in sophistication.

Berners-Lee, Tim (1955–)

Tim Berners-Lee is the mind behind the creation of the World Wide Web used by millions around the world at any given time of day. His innovative idea made the complicated process of sharing information via computer an easy task. An Englishman by birth, Berners-Lee's invention changed the world.

Berners-Lee was born in London, England, on June 8, 1955. Both his father, Conway Berners-Lee, and his mother, Mary Berners-Lee, were mathematicians. His parents' career path would be of great influence growing up: Berners-Lee constructed a device that allowed him to control his model trains. This interest in the field of electronics and mathematics followed him into adulthood, and he graduated with a bachelor's degree in the field of physics from the Queen's College at Oxford University in 1976. Then he worked for a variety of firms in Britain, including the major telecommunications firm Plessey Telecommunications, for about two years.

Berners-Lee then worked for Conseil Européen pour la Recherche Nucléaire (CERN), a laboratory in Geneva, Switzerland, that concentrates on particle physics. Though his stay at CERN was not very long, he did some important experiments there. To document his work and personal life, he used Enquire, a software program that he wrote that used "hypertext," which allows one text document to be linked to several others at once. Berners-Lee used that idea to experiment with on his own computer. The Enquire program slowly made its way to the computers of many other scientists working for CERN. Though many were open to the concept, some were not.

After six short months with CERN, Berners-Lee made his way to Image Computer Systems, an English firm, in 1981. There, he designed hardware and communications software for printers for three years. But he was invited back to CERN to perform further research and returned in 1984. The firm had ceased to work with Enquire, but it appreciated and recognized his innovation and knowledge. At CERN, Berners-Lee

experimented and proposed ways to use the concept of hypertext to allow people to obtain and share information.

In 1990, Berners-Lee's ideas became a reality. With the assistance of those from CERN, he developed hypertext transfer protocol (HTTP), hypertext markup language (HTML), and the uniform resource locator (URL). Each component was of high importance, working together to allow the emergence of the World Wide Web. The purpose of the hypertext transfer protocol was to better organize information that was to be viewed or shared, by proper storage. Hypertext markup language (HTML) essentially categorizes the different types of information in any document, such as images or text. And last is the uniform resource locator (URL), which can be best described as a code or address given to a certain document that can be easily referred back to when needed. Berners-Lee wanted everyone to have access to information, which led him to create what is now known as the World Wide Web. In October 1990, those within CERN were the only ones who had access to it.

In summer of 1991, Berners-Lee finally allowed public access to the World Wide Web. At first, Berners-Lee provided a document that taught the public step by step how to set up a Web server as well as to how to set up a site of one's own. It had a slow start initially, but it picked up very quickly once word spread. Later, many approached him about making a profit from such an innovative, world-changing invention, but he declined them all. He recognized that it was not perfect, so in 1994, he founded the World Wide Web Consortium (W3C) to enhance and improve it. As a senior researcher and holder of the founder's chair at the MIT Computer Science and Artificial Intelligence Laboratory (CSAIL), Berners-Lee is also a member of the advisory board of the MIT Center for Collective Intelligence. In 2011, he joined the board of trustees of the Ford Foundation. Ten years later, he found himself being knighted by Queen Elizabeth II, and he would continue to receive recognition for this life-changing invention.

Berners-Lee did not look to profit from the World Wide Web; neither does he want anyone else to. He wants it to be open for everyone to use. He will not allow any entity to censor or interfere with that right.

The Web is a very powerful tool that has changed the way we all think and approach information gathering and sharing.

Boston Tunnel

The Boston “Big Dig” tunnel is one of the largest infrastructure projects in the United States today. Known officially as the Central Artery Project, the Big Dig commenced planning in 1982 to aid heavy traffic congestion on the city’s main highways. As vehicular presence rapidly grew in the 1990s, the deteriorating six-lane central artery, Interstate 93, could no longer uphold the swell of activity. Traffic was heavy for more than half the day, and the accident rate was the highest national average of all urban areas—nearly quadruple. By 2010, this severity was estimated to cost motorists \$500 million annually in wasted gas, accidents, and late service charges. Consequently, Boston’s economy suffered greatly and was in need of transportation improvements.

Under the oversight of the Massachusetts Turnpike Authority, construction began in 1996, and the project was completed in 2007. The Big Dig had two main goals components: to restructure the overhead central six-lane system into a multilane underground tunnel named the Thomas P. O’Neill Jr. Tunnel, which crosses the Charles River; and the extension of Interstate 90 from South Boston to Logan International Airport through the construction of the Ted Williams Tunnel.

The project also included the construction of a 10-lane hybrid bridge named the Leonard P. Zakim Bunker Hill Bridge and the Rose Kennedy Greenway. Once the tunnel was commissioned, the Authority began demolition on the old Central Artery to free up space and use the area for future development.

Due to the specifications of relocating an elevated highway into a tunnel, the Big Dig became one of the most daunting and expensive projects in the nation’s history. No project of this stature had ever been undertaken in a significantly dense and urban area. In its entirety, the Big Dig cultivated 161 miles of lanes, half of which were in tunnels and roughly eight on highways. Sixteen million cubic yards of soil had been excavated from the site, while 3.8 million cubic yards of concrete were installed. Concern grew regarding the elevated highways and the masses of newly installed concrete. Engineers decided to excavate farther under the tunnel and place 26,000 feet of steel-reinforced slurry walls, the largest amount ever used in North America. These structures served as walls for the tunnel while also aiding the construction of the highways above.

Initially, the Big Dig was estimated to cost around \$2.6 billion and was planned to be completed in 1998. However, several delays, design flaws, leakages, and a fatal ceiling collapse heavily prolonged the project’s duration and costs. At its peak from 1999 to 2002, the project cost around \$3 million per day or \$110 million per month, with 5,000 workers on-site. Upon its completion in 2007, the cost for the Big Dig totaled over \$14.6 billion—significantly higher than expected. It was the most expensive highway super project in American history. Over \$400 million was paid in restitution by the overseeing engineering consortiums, Bechtel and Parsons Brinckerhoff, for injuries as a result of various structural mishaps.

Further obstacles also arose in regard to the site’s environmental impact. Agencies were concerned that with extraction of landfill and earth, several toxins would be released into the atmosphere. This would disrupt the habitat of several million rats, causing them to seek new residence in streets and homes. Also, to remove tons of landfill, excavators needed to freeze the ground to extract it more efficiently. This posed an environmental issue because the contaminated fill

allowed more toxins to be released into the atmosphere instead of the lesser amount via traditional and safer methods.

On July 10, 2006, a fatal collapse occurred within the confines of the Ted Williams tunnel. A 26-ton panel off the tunnel's ceiling fell, leaving one woman dead and another injured. Outrage erupted after this tragedy, as it stemmed from a major design flaw and reflected poorly on the engineers responsible. Despite the project's \$14.6 billion cost, cheap and improper adhesive had been used to hold the panels on the ceiling. Settlements were reached in response to the families of both the injured and deceased, while the state of Massachusetts launched a civil suit against the aforementioned Bechtel and Parsons Brinckerhoff. The adhesive supplier, Power-Fast Epoxy, was indicted on the charge of involuntary manslaughter.

Apart from legal action, investigation and repairs decommissioned the tunnel for almost a year, causing Boston's traffic to congest once again. It was also mentioned that a heart attack victim lost his life due to traffic jams as he proceeded toward Boston Medical Center. Other issues involved severe leaks and light fixtures that were prone to collapse. The guard rails in the tunnels were also recalled due to their squared edges, which were responsible for impaling several who had been ejected from their cars in the midst of accidents. After the eighth incident, the Massachusetts Department of Transportation removed a portion of the dangerous rails.

After the Central Artery Project's development, Boston's transportation and quality of life drastically improved. The city saw a 62 percent reduction in the vehicle-hours to travel on the new highways, saving Bostonians and visitors around \$168 million annually. The city also saw a 12 percent decrease in its carbon monoxide levels and recycled the excavated dirt to top landfills. Neighborhoods were able to reconnect in the absence of the former highway. In the highway's stead, the project generated more than 300 acres of parks and green space. Several of these acres are planned to be developed into residential and retail communities.

CD and DVD

Compact discs and digital versatile discs, known by the shorthands "CDs" and "DVDs," are data-storing devices containing media read by laser. While the two types of discs are fundamentally similar, there are some key differences between them. CDs have a slight structural difference, lower storage capacity, and slower rotation speed than DVDs. DVDs possess the benefit of not degrading each time they are read, allowing a longer lifespan. CDs and DVDs were the mainstream way of delivering multimedia to people across the globe for many years. However, wireless and discless methods of transmitting data, such as streaming, have gained momentum and popularity in the modern age due to efficiency, ease of use, low cost, and perpetually growing libraries of media.

While the creator of the compact disc cannot be credited to any one entity, James T. Russell, an American inventor; Sony; and Philips are key figures in the creation of the CD in circulation today. Sony and Philips, international electronic companies, began creating and refining the compact disc in the late 1970s, a decade after it was originally created by Russell. Through cooperation with Sony, the final diameter was 12 centimeters, and the initially proposed resolution (accuracy) of 14 bits was increased to 16. CDs were wildly popular in the 1980s, when they were first introduced to the public, and well into the 2000s because they were affordable and accessible as they transported media, graphics, and other electronic information efficiently.

Different versions and capabilities of compact discs were developed since the original inception of the first compact disc known as a CD-ROM. While structurally similar, the types of CD differ mainly in their recording and rewriting capabilities as well as storage capacities.

Introduced in the 1980s, compact discs (CDs) offered data storage technology that took up less physical space and was a higher quality option compared to earlier data storage technology. CDs replaced floppy discs and DVDs replaced VHS tapes. CDs were replaced by flashdrives within ten years. (Corel)

The “compact disc read-only memory” (CD-ROM) is neither recordable nor rewritable once the original data is loaded onto the disc. Once its maximum capacity is reached, the disc is considered full and is unable to accept any more data. This type of disc has been a popular choice for video game and software companies for distributing their media to consumers. The CD-ROM has proved reliable and efficient, which is why it has remained relevant even as CD sales have declined in recent times.

The “compact disc-recordable” (CD-R) starts out blank and allows users to record over the empty data spiral, similar to the function of a floppy disk. This engraved information becomes a permanent etching on the disc, which can hold anywhere between 74 and 80 minutes of data.

Similarly, the “compact disc-rewritable” or CD-RW is a blank disc that allows the empty data

spiral to record information that can be erased and recorded over, as if the disc were still blank. Erasing and rerecording data is done with lasers that reach different temperatures and interact with the metal alloys within the disc.

“Digital versatile discs” (DVDs) are high-capacity discs developed in 1995 and cocreated by Philips, Sony, Toshiba, and Panasonic. These discs’ storage capacity is measured in gigabytes, ranging anywhere from 4 up to 18 gigabytes. Since they store more than a standard compact disc, DVDs are commonly used to store motion pictures, video games, and some computer programs. From the late 1990s through the 2000s, DVDs were integral to bringing higher-definition audio and visual media to households that were previously seen only in commercial locations such as movie theaters.

In 2006, a new type of DVD emerged: the Blu-ray disc. Developed by the Blu-ray Disc Association, it

can store up to 50 gigabytes of data and produce a clearer picture due to the shorter wavelength of the blue-violet ray that reads the disc. The Blu-ray disc format was intended to take over the DVD industry, but its reception was not overwhelming. It has struggled to maintain a strong presence in light of continued DVD production, streaming media services such as Netflix and Hulu, as well as increased costs associated with making and selling Blu-ray discs.

There have been innumerable benefits from the advent of digital discs not only for the electronics and entertainment industries, but for the public, because of the amount of information it can consume, create, and reproduce. However, looking forward, digital discs are falling in popularity compared to streaming data over Internet networks, which is convenient and efficient. Without a need for digital discs, which are susceptible to scratches, breakage, deterioration, and loss, the public has begun to favor the alternative method of accessing data via streaming or the “cloud,” the invisible online network that allows for downloading and uploading of multimedia material over Internet connections. This has led entertainment companies such as Spotify, iTunes, and YouTube to serve households and businesses everywhere with data that exceeds disc quality and without the limitations of retaining, using, and caring for physical discs.

CD-ROM

A “compact disc read-only memory” (CD-ROM) is a digital disc containing binary data read by a low-powered laser. James T. Russell, an American physicist and inventor, originally created the concept of compact discs in the 1960s. The disc was later refined and manufactured by a joint operation between Sony and Philips in the 1980s. CD-ROMs replaced both long-playing (LP) records as well as 3.5-inch floppy disks because of their versatility and ability to carry nearly 500 times the amount of data than a floppy disk and therefore larger amounts of personal and commercial data such as music, graphics, and programs. At their inception, CD-ROMs were seen as revolutionary, and they eventually led the way to the advent of recordable, rewritable, and digital versatile discs (DVDs).

Over his lifetime, Russell patented more than 50 inventions, with close to 25 of those relating to CD-ROM technology. His initial inspiration for the CD-ROM came as he noted that the physical contact between vinyl LP records and their players caused deterioration over time. He invented a disc, and subsequently a device to play it, that eliminated the need for such contact. Russell’s prototype was a rudimentary disc containing data that could be read by spinning counterclockwise while suspended above a light beam, which was made possible by laser technology.

Unfortunately, Russell found his invention hard to market to other companies at the time. Two decades later, realizing the potential of such technology, Sony and Philips partnered on refining and improving the concept. Through a process of combining polycarbonate, aluminum, and film lacquer, the CD-ROM was born and revolutionized the way material was marketed, sold, and distributed. CD-ROMs proved beneficial to software, gaming, and entertainment industries alike because of their read-only capabilities and their portability.

CD-ROMs manufactured for commercial and personal use are created by using a master disc as a way to replicate data in a mass production setting. To create the first disc, a film coating is applied over a glass disc, and information is embedded into it via a laser.

This creates pits and “lands” in the glass, which creates the mother, or master, disc. A metal alloy is then poured over this surface to create the father, or stamper portion, of the master set. It is this stamper that is applied over layers of polycarbonate in replication machines to create CD-ROMs with the original master information embedded on them. After a reflective layer, protective layer, and optional label are applied over the polycarbonate, the CD-ROM discs are ready for distribution.

CD-ROMs are inserted into a computer via a caddy or directly into a dedicated slot for compact discs. Inside the computer or device, a single laser beam is focused at the rotating disc. The laser beam records and translates the landscape of the transition from pits to lands embedded on the disc in binary code, represented as ones and zeros. This information is then interpreted by the computer, which then produces the media found on the disc for the user to utilize.

CD-ROMs were favored over storage solutions such as vinyl records and floppy disks because of their ease of use, portability, storage capacity, and low cost associated with production and resale. Over time, the ever-growing technological advances and security implementations in digital media resulted in the decline of the use of CD-ROMs. CD-ROMs, just as other compact discs, are susceptible to breakage and the violation of copyright laws, and they suffer from limitations on the amount of data they can store. Also, because CD-ROMs are read-only, they are severely limited in the amount of use a consumer can get out of them.

While CD-ROMs were a mainstay for a few decades, they were slowly phased out in favor of alternatives, including DVDs and Blu-ray discs. Eventually, digital discs will be phased out completely due to the advent of streaming, which allows data to be transferred digitally via the Internet and became the preferred method for distributing and deciphering data by the early 2010s.

Computer/Information Technology

Even though computing-type technology can be traced to ancient times, computer/information technology (CIT), the storage, manipulation, and transmission of information in digital form, truly got its start during World War II (1939–1945). Since that time, CIT has gone through several iterations. With each generation of CIT, humanity has benefited from new tools, but CIT has also produced some philosophical and ethical dilemmas. Although we can’t predict the future with certainty, some experts have voiced concern over certain aspects of CIT’s future evolution.

The abacus, a counting machine, was invented during the 4th century BCE. Later developments included a device to predict the motions of the solar system and a device to calculate numbers. Unlike these pre–Industrial Age devices, the machines from the first CIT generation (1939–1954) were heavy and huge, ran on vacuum tubes, and were powered by electricity. During the war, the U.S. military used “the Colossus” to decode German secret messages. In 1945, the Ballistics Research Laboratory (in Maryland) developed the Electronic Numerical Integrator and Computer (ENIAC) to assist in the preparation of U.S. artillery firing tables.

After the war, Remington Rand sold the Universal Automatic Computer (UNIVAC) to the U.S. Census Bureau. In 1952, an upgraded UNIVAC was used to calculate the winner of the presidential election. Second-generation computers (1954–1959) generated less heat, were smaller, and weighed less than their predecessors, because they used transistors rather than vacuum tubes. In 1957, International Business Machines (IBM) sold computer model 608, the first computer on the commercial market.

The use of integrated circuits characterized CIT's third generation (1959–1971). During the 1960s, the ability to draw, type, and edit on a computer screen rather than on paper was realized with Sketchpad (1962) and an early word-processing program (1968). In the 1960s, IBM produced SABRE, the first airline reservation tracking system, and the U.S. Department of Defense began working on ARPANET (the forerunner of the Internet). The microprocessor was the cornerstone of CIT's fourth generation (1971–2011).

In 1973, Xerox introduced Ethernet, the first environment that allowed computers to communicate with each other. During the 1970s, Apple developed the first personal-size computer. In 1980, Bill Gates's work with IBM resulted in the creation of Microsoft, which became the largest software company in the world. In 1987, Apple developed HyperCard (a predecessor of the graphical environment later used on the World Wide Web), which allowed for the use of hypertext. The World Wide Web appeared in 1991. The massive content on the Web necessitated the development of various Web browsers, including Mosaic (1993), Netscape (1994), and Internet Explorer (1996). The easy access to information at users' finger tips ushered in the information age.

As CIT increasingly permeated everyday life, it became indispensable in many areas, including business, medicine, education, government, and the military. Some negative physiological effects of the constant use of computer keyboards included repetitive stress injuries, carpal tunnel syndrome, tendonitis, and tennis elbow. In the digital environment where data was transmitted both wirelessly and through wires, data encryption and antivirus software became the two most common reactions to the chief modern CIT issue: cybersecurity. In this regard, cyber criminals (hackers) were notorious for breaking into certain "secured" computer systems, such as those protecting bank accounts and national defense systems.

CIT's effects on social life have been profound. CIT has served to enhance freedom of speech in nations that would otherwise restrict it. Universities and colleges have increasingly offered online courses, which has made education much more accessible. However, other effects of CIT have been less desirable. For example, sociologists have feared that at

home, many people would interact with their "smart" devices more than they did with other people.

By the 2000s, video gaming became popular on home systems that allowed players to interact with a wide circle of people online. The Internet provided access to so many communities that it was not difficult for people to find those that shared their interests. Although it has been much more convenient for people to attend virtual communities than real ones that are many miles away, philosophers have questioned whether extended exposure to online friends who agreed with them would make them less tolerant to people in the real world who disagreed with them. For some people, virtual online communities have functioned as substitutes for real social groups.

In the work environment, e-mails, text messages, and video conferences have reduced the need for workers to gather. Some philosophers have pointed out that, in the absence of available credible information, the massive amounts of readily available unregulated Internet content could misinform people. Furthermore, Internet information can serve as a lens through which people view the world and persuade them to take certain actions. In other words, the philosophical question became whether humans are in control of CIT or if CIT is in control of humans.

Since the beginning of humanity, people have been locked into the cycle of physical life. They are born, grow, reproduce, and then die. Those who have lived to old age endure a body that has become increasing feeble. In the light of these facts of the human experience, some people have longed to break the cycle through technology. The idea was to develop a process by which doctors could transfer the contents (memories, knowledge, and consciousness) of human brains to durable robot bodies. After the data transfer, humans could theoretically live forever. Although the not-yet-existent technological process seems desirable to some, most people cringe at the idea of abandoning their human bodies.

In truth, the future fifth evolution of CIT is unknown, but experts have predicted two major developments: enhanced virtual reality (VR) and advanced artificial intelligence (AI). VR, a computer-generated simulation of a three-dimensional image and/or environment, was introduced in the 1960s. Since that time,

CIT has evolved with the use of headsets and the ability of the wearer to interact (through sight and sound) with VR displays. Doctors and medical students have used VR to perform practice operations, and with the use of VR, pilots have gained many hours of valuable flight simulation experience. In a similar way, astronauts have conducted training exercises to practice for complex maneuvers during space missions.

Scientists have been working on developing AI software to perform tasks normally requiring human intelligence since the 1950s. In the 1990s, IBM introduced Deep Blue, a computer designed to play chess without human assistance. The “thinking” ability of Deep Blue exceeded that of all other chess computer games with the number of moves it could consider before making a calculated decision. In 1997, Deep Blue became the first chess computer to defeat a world-renowned human chess champion. However, some critics claimed that Deep Blue’s knowledge base was too narrowly focused on chess and, therefore fell short of authentic human intelligence.

In the early 2000s, IBM rolled out Watson, a computer capable of answering questions posed in natural language. In 2011, Watson competed against two former champions on the quiz show *Jeopardy!* Watson’s ability to quickly access specific information from 200 million pages of content earned it the first-place prize of \$1 million. Since this highly publicized display of a “thinking machine,” business leaders have employed Watson in an effort to run more efficient enterprises. In 2016, Watson was used to conduct weather forecasting. In 2017, the tax preparation company H&R Block used Watson to enhance its client experience.

Some scientists and CIT experts (including Stephen Hawking and Bill Gates) have voiced concerns about the possibly disastrous outcome of a human reliance on AI. Since CIT systems have the ability to evolve much faster than humans, these experts believe that AI can develop to a point where humans may lose control over their own creation. This group has argued that human-designed safeguards, although necessary, are merely temporary solutions, because computer superintelligence would eventually supersede human intelligence. Although these scenarios may sound more like science fiction than reality to many people, Gates and others do not understand the general lack of

concern. According to this alarming view, as CIT becomes engrained in many facets of human life (from the operation of traffic lights to the deployment of defense systems), the level of AI development may determine whether fifth-generation CIT continues to function as a human tool or becomes a threat.

Cray, Seymour (1925–1996)

Considered the creator of supercomputers, Seymour R. Cray was born on September 28, 1925, in Chipewaga Falls, Wisconsin. As a high school student, Cray studied electrical engineering and in 1943, he joined the U.S. Army, serving in the capacity of a communications soldier. In the European theater of World War II, he participated in the Battle of the Bulge, among others, before being recruited to a unit serving in the Philippine Islands. After he returned from war, Cray used his GI Bill to attend the University of Minnesota, where he received a bachelor of science degree in electrical engineering in 1950, followed by a master’s degree in applied math in 1951.

Engineering Research Associates (ERA), based in St. Paul, Minnesota, hired Cray to help in its project

constructing cryptographic equipment for the U.S. Navy. There, Cray worked on a wide variety of computer technologies ranging from vacuum tubes and magnetic amplifiers to transistors while also designing his first supercomputer, the 1103—also known as Univac I, the first computer to use random access memory (RAM).

In 1957, Cray left ERA to join Control Data Corporation (CDC), where he served as acting director and later as senior vice president until 1972. At CDC, he built the fastest computer then in existence, the CDC 1604—the first fully transistorized commercial computer, which worked without vacuum tubes. His next invention, the CDC 6600, is considered the world's first supercomputer with a processing power of nine megaflops (Mflops)—1 million floating-point operations per second—and cooled by Freon, another first. In 1963, Cray built the CDC 7600, running at nearly four times the capacity of the last model, and in 1968, Cray designed the CDC 8600 using four processors that all shared one memory core.

When board members of the CDC decided to phase out development of large-scale scientific computers, Cray left to found his own company, Cray Research Inc., based in his hometown of Chippewa Falls, Wisconsin. There, in 1976, Cray developed the Cray-1 TM vector supercomputer, which introduced integrated circuits to replace transistors. The Cray-1 had a processing power capable of 170 Mflops. From 1972 to 1977, he served as director, chief executive officer, and the president of Cray. In October 1977, he relinquished the presidency of Cray Research but remained chief executive officer and chairman of the board.

Cray resigned as chief executive officer in 1980, and in 1981, Cray stepped down as chairman of the board. He wanted to devote all his time to the development of the Cray-2 TM project. The new innovation for the Cray-2 TM came in utilizing gallium arsenide processing chips. In 1985, Cray created the Cray-2 computer system by in turn creating the gigaflop, equivalent to 1,000 Mflops, a barrier no one had thought could be broken. Cray experimented with gallium arsenide as an ultrafast semiconductor material, but he returned to the use of silicon chips. He also

introduced the use of Fluorinert, an inert fluorocarbon liquid, as a coolant.

In 1989, Cray founded the Cray Computer Corporation, based in Colorado Springs, Colorado, to work on the Cray-4, but the company shut down in 1995 due to financial pressures. In early 1996, Cray started SRC Computers Inc., but he died a few months later, on October 5, 1996 at the age of 71, due to injuries suffered in an automobile accident.

For his work, Cray has been honored with the W. W. McDowell Award by the American Foundation of Information Processing Societies and the Harry H. Goode Memorial Award for his contributions to large-scale scientific computer design and the development of multiprocessing systems.

Dell, Michael “Saul” (1965–)

Founder of Dell Inc., manufacturers of the Dell computer, Michael “Saul” Dell was born to working parents Alexander, an orthodontist, and Lorraine, a stockbroker, on February 23, 1965. At a young age, Dell’s mother influenced him toward a career in business with frequent topics raised during dinner. He took to it quickly. At the age of 12, Dell displayed a natural affinity for business by buying and reselling postage stamp collections, netting himself a profit of \$2,000.

At the age of 15, Dell developed an interest in technology, in particular in personal computers. He convinced his parents to allow him to buy the new Apple II personal computer with money from his savings. On

the same day that he bought the brand-new machine, Dell dismantled the computer in an attempt to understand its inner workings. This was the start of what would become a lifelong obsession with technology and computers. Throughout the rest of his teenage years, Dell continued to immerse himself in the culture of computers, from learning enough to be able to help fix his friends' computers to skipping school to attend the annual National Computer Conference.

In 1983, Michael Dell started his first year of college at the University of Texas. Though his parents had hoped he would study to become a physician, Dell had other plans. While in school, Dell continued to help people fix and upgrade their computers for a profit. Dell decided to drop out of college and register Dell Incorporated as an official business. He never returned to the University of Texas.

By 1984, after its first full year of business, Dell Incorporated earned over \$6 million in sales. One of the biggest ways that Dell Inc. stood out from the competition was the company's philosophy of selling computers directly to customers via mail rather than through a middleman's storefront. This required supply chain innovations and a promise of solid customer service, since there would be no in-store counter to go to for questions or repairs. In a variety of interviews, Dell explained that often, while he was on the Internet, he scanned forums for user opinions of his company and its products, and he used that feedback to further improve the company.

Five years later, in 1989, he and Susan Lynn Lieberman married. They would have four children. In 1992, Dell became the youngest CEO of a Fortune 500 company. Throughout all this growth, Dell also created a track record of being very philanthropic. In 1999, he and Susan established the Michael and Susan Dell Foundation, a private charity that has provided aid to people in need, such as victims in Southeast Asia of the 2004 Indian Ocean earthquake and tsunami. The charity has also donated to Dell's former university, the University of Texas.

By 2000, after 17 years of business, Dell was a billionaire, and Dell Incorporated was one of the models of success in the business of computer sales. After 30 years in business, the company is still thriving. In

2016, Dell expanded his interest in technology companies by acquiring the enterprise software and storage company EMC Corporation.

Dell Incorporated has proven Michael Dell to be one of the biggest pioneers in forming the technology landscape of today. With the philosophy that technology is about enabling human potential, Dell has been instrumental in ushering in the age of information technology and personal computers.

Digital Photography

Digital photography is a type of photography that uses arrays of electronic photodetectors to capture images instead of photographic film and then stores the images as a computer file instead of as negatives or in print. In 1975, Steven Sasson, an engineer at the Kodak company, helped invent digital photography.

The first prototype of the digital camera was made up of Motorola parts with a Kodak movie camera lens. Then, connected to the bottom of the camera was a half dozen circuit boards wired together. The inside of the camera was more complex. To create digital photography, Sasson had to find a way to save the captured image and view it afterward. He decided to use a cassette tape to capture an image, but he needed to figure out how to store the image on it. He solved this

by using digitalization, a process that turns electronic impulses into numbers.

Using this process, he then stored the images in random access memory (RAM) and then on the cassette tape. The cassette tape would be taken out of the camera and placed into a computer so the image could be viewed. This camera took 50 milliseconds to capture an image and then an additional 23 seconds to save it on the cassette tape. The images were in black and white only until digital photography slowly advanced. Now, it is more convenient and easier to capture an image with digital photography than it was in 1975.

Other camera companies developed their own digital cameras. In 1991, Nikon sold the first digital camera. It did not look anything like the Kodak camera and was mainly used for photojournalism. Then in 1995, Apple came out with the Quick Take 100, which was more affordable. Its photographs could be viewed by using a serial cable connected to a computer.

1995 became the year for consumer digital cameras. Companies making them included Casio, Kodak, and Sony. Now we can do digital photography with cell phones and more advanced digital cameras. We can take pictures at any place and at any time. Digital cameras now vary in size depending on intended use. Some are simple, and some are for professional use. Now there are digital cameras the size of the cassette tape that was first used to store digital images.

Digital photography has changed photography exponentially. Consumers can take as many photographs as they want, limited only on the amount of storage space a camera or memory card has, not the number of exposures allotted per roll of film. We can also view images immediately upon taking them. If an image is blurry or otherwise unsatisfactory, it can be deleted instantly. With continually updated software, we can modify any photograph. There are options to change the exposure of the image, do color correction, or change the image from color to black and white. With the advances in digital photography, there are countless possibilities for manipulating images.

When digital photography first appeared, many camera companies argued that film should not be abandoned. But the use of film began a slow decline. Even though both methods are still used to capture images, they are different in many ways. One difference is in the resolution. Digital photography has high resolution because of software capabilities. A camera has digital image sensors that can be programmed for certain resolutions by counting the number of pixels within the parameters of the image. Film does not have pixels; it uses angular resolution.

With film cameras, the type of camera and film determines the size of a picture. There are different types of film and different camera formats as well. In digital photography, how you view the image can affect the size of a picture. Viewed on the camera, it is the size at which the image was taken, but if it is uploaded to a computer, there is an option to enlarge it or make it smaller. The range at which a photograph is taken can have an effect on the image as well. And with film, once a photograph is taken, it cannot be undone.

One important difference between digital and film photography is in cost and convenience. While this depends on what type of camera is used (and the cost of memory cards and film can vary), film is generally more expensive than digital memory. And, once the storage on the card is full, images can be transferred to a computer or other storage and deleted from the card. The card can then be reused. Film can only be used once, and images on it can eventually fade.

Primary Document: Excerpt from the Patent for Kodak's Digital Camera (1978)

In December 1978, Kodak issued a patent for the first digital camera, the electronic still camera. It was invented by Steve Sasson, one of its scientists. To store the digital photograph, Sasson used digitalization. He turned the electronic impulses into numbers and stored them in RAM memory. Afterward, the image could be viewed on a screen. This excerpt from the patent provides details of how the camera captured digital photographs and was hooked up to a screen to display them. It discusses the structure of the camera and the use of digital photography.

Description of the Prior Art

Conventional cameras employ a shutter for exposing for a limited duration photographic film located at a film exposure plane. Film processing solutions are required to produce a visible image of the photographed scene. As is well known, processed photographic film may not be reused.

Recently, considerable effort has been given to the development of solid-state elements for imaging purposes. Such elements offer an advantage over photographic film in that, theoretically, they can be reused any number of times for imaging.

A solid-state imaging element of the type known as a charge transfer device can include a semiconductive substrate doped with majority carriers and covered with a thin insulating film upon which is located an array of electrically conductive electrodes. A depletion region or potential well is formed within the semiconductor under electrodes biased by a voltage of the proper polarity. The use of a charge transfer device involves the basic concept of forming a charge pattern consisting of packets of minority carriers in the potential wells. In the course of an

optical imaging process, photons incident upon the semiconductor generate minority carriers within these potential wells in proportion to the amount of light impinging upon the semiconductor in the near vicinity of each well. These packets can be transferred through the semiconductor by sequentially biasing the electrodes. The potential wells effectively “move” through the semiconductor sweeping the minority carriers along within the wells. At an appropriate location these packets may be detected, for example, by removing them sequentially from the semiconductor by means of a reverse-biased diode coupled to transfer electrodes. An arrangement for read-out of information from a charge transfer device is disclosed in IEEE Transactions On Electron Devices, Vol. ED-20, No. 6, June 1973, in an article entitled “interlacing In Charge Coupled Imaging Devices,” by Carlo H. Sequin.

As with conventional photographic film, to obtain a scene image having a proper contrast, the imaging element must not be overexposed, or, in other words, the potential wells must not be saturated with minority carriers during the exposure interval. However, even in the absence of illumination, the regions constituting the potential wells tend to saturate with the passage of time by means of the thermal generation of minority carriers. Carriers generated in this manner constitute an unwanted signal commonly known as a “dark current.” It is important that this signal be only a small fraction of the signal produced by incident illumination, particularly if the dark current is nonuniform over the imaging area.

Elion, Gertrude (1918–1999)

Together with fellow scientist George Hitchings, the American pharmacologist and biochemist Gertrude B. Elion revolutionized the field of pharmaceuticals and medicine by developing a systematic method to

manufacture drugs. Her innovations included the production of the first medications used to treat leukemia and the first immune-suppressive agent used during organ transplantation, as well as other drugs to treat malaria, gout, toxoplasmosis, and many viruses. She won a Nobel Prize for medicine in 1988.

Gertrude Belle Elion was born in New York City on January 23, 1918. Her parents were Lithuanian

Biochemist Gertrude Elion and coworker George Hitchings were awarded the Nobel Prize in Physiology or Medicine in 1988. Their work in developing drugs to treat leukemia and AIDS helped millions of those afflicted to live fuller lives. (Bettmann/Getty Images)

and Polish immigrants who lost much of their wealth during the Wall Street crash of 1929. After graduating from high school at age 15, she only had few educational choices due to her family's poor economic conditions. She was accepted at the women's Hunter College in New York, where she obtained her BS in chemistry when she was just 19 years old. She earned her MSc degree at New York University four years later, in 1941. At NYU, Elion struggled with financial hardship, and afterward, gender bias prevented her from finding a stable job as a chemist. She worked as a biochemistry teacher at New York Hospital School of Nursing, a food quality supervisor at A&P supermarkets, and a research chemist at Johnson & Johnson.

In 1944, Elion was hired at Burroughs Wellcome Laboratories (today known as GlaxoSmithKline) in Tuckahoe, New York, as an assistant to Dr. George Hitchings, who gave her progressively more responsibility. The two discovered a new way to design compounds by exploiting the biochemical differences between human cells and pathogens to block the spreading of infections. They also found a new method to selectively force cancer cells into incorporating artificial substances that stopped their growth without affecting healthy cells. Hitchings and Elion formulated a plethora of new substances that have saved millions of lives by providing new, effective treatments for viruses, urinary tract infections, malaria, gout, leukemia, and meningitis. Their formulas also help during organ transplants.

Elion's work focused almost entirely on the purines, a group of organic compounds found in organ meats, vegetables, and seafood. Any substance that interacts with the pathways that control purine production and breakdown may severely damage a cell's DNA sequences, causing its death. Thanks to recent breakthroughs in biochemistry that elucidated those pathways, in the mid-1950s, Elion and Hitchings developed the first two drugs for the treatment of acute leukemia: mercaptopurine (also known as Purinethol or 6-MP) and thioguanine.

Together with Roland K. Robins and Wayne Rundles, she also found that allopurinol, a compound originally synthesized as a potential antineoplastic agent, was indeed effective to treat gout. In 1963, she developed azathioprine, the first immunosuppressive agent that could block the production of antibodies. Together with glucocorticoids, azathioprine was the standard treatment to suppress the immune system's rejection of foreign tissues during heart and kidney transplants for the next two decades.

She also developed the antimalaria agent pyrimethamine, the chemotherapy agent nelarabine, and the antibiotic trimethoprim. In 1967, Elion was appointed head of the Department of Experimental Therapy, which contained several different sections that coordinated their efforts to develop new drugs, including immunology, virology, chemistry, pharmacology. It also had a tissue culture laboratory, where Elion developed the world's first antiviral drug—acyclovir—

which is still used today to treat herpes, shingles, and chicken pox.

Elion was also adjunct professor of pharmacology and of experimental medicine at Duke University from 1971 until her retirement. Although she officially retired in 1983, Elion kept serving as an advisor for the World Health Organization and became president of the American Association for Cancer Research. She also actively contributed to the development of azidothymidine (AZT), the first drug approved for the treatment of AIDS. Still holding the title of scientist emeritus, Elion was awarded the Nobel Prize in Medicine in 1988 together with Sir James Black and her colleague George Hitchings.

Later in life, she was presented with additional awards, such as the National Medal of Science that she received from President George H. W. Bush in 1991. During the same year, she was also the first woman to be inducted into the National Inventors Hall of Fame, and in 1995, she was elected a foreign member of the Royal Society. Over the course of her career, she received 23 honorary degrees and held a total of 45 patents in medicine. Elion died at the age of 81 on February 21, 1999, in Chapel Hill, North Carolina.

Floppy Disk

The first memory disk was created at IBM and introduced to the public in 1971. Invented by IBM engineers led by Alan Shugart, floppy disks were a significant advancement in the way information could be accessed, stored, and distributed. The nickname “floppy disk” was due to the flexible materials these disks were composed of. Coated with magnetic iron

oxide, the earliest version featured an eight-inch plastic disk. The floppy was designed for loading microcodes into the controller of the IBM 3330. The Merlin disk pack file could store 100 megabytes of data. Due to advancements in hardware, the floppy disk later became known as the “diskette” and became a slimmer, 5.25-inch disk that was used in IBM’s first personal computer in 1981.

The 5.25-inch diskette was developed in 1976 by Alan Shugart of Wang Laboratories. An Wang of Wang Laboratories wanted to redesign the floppy so it could be used with its desktop computers. The slimmer size was decided on by engineers Jim Adkisson, Don Massaro, and An Wang at a bar when Wang used a drink napkin to show he wanted the disk to be “about that size”—which turned out to be 5.25 inches wide. The capacity of information storage during this time was measured in kilobytes as compared to the larger formats of modern portable drives measured in gigabytes. By 1978, more than 10 manufacturers were producing 5.25-inch floppy drives that were capable of storing approximately 1.2 MB of data.

There were more improvements over the years. Sony introduced a 3.5-inch version of the floppy drives and diskettes in 1981. Made with hard plastic cases, they weren’t flexible but continued to be called floppy disks. These diskettes evolved from storing 400 KB of data to 720 KB (“double density”), and finally, they had a 1.44 MB, “high-density” storage capacity. With improvements in design, storage capacity, and style, the new floppy disk gained more popularity and recognition, and the 5.25-inch version had a significant plunge in sales. This old version’s recording surface was easily damaged by fingerprints where there was open access to it, and without a hard case, it was easily bent.

Composed of a drive motor, stepper motor, read/write heads, circuit board, and a mechanical frame, the diskette has relies on its hardware to work properly. The floppy disk functions similarly to a cassette tape, as they are both composed with iron oxide, a ferromagnetic material. The floppy is also similar to recording tapes because it is a circle of magnetic material grabbed by its center and spun like a record inside its housing. Much like the head on a tape deck, the read/write head contacts the recording

surface through an opening in the plastic covering, or shell.

From the late 1970s through the 1990s, floppy disks were recognized as an almost universal data format whose primary function was to store data, but it became a file transfer system. The floppy offered an inexpensive and reusable way to store information with the option of deleting files, and it became an iconic part of the technological evolution. Notable forms of the floppy disk include the original 8-inch disk, the 5.25-inch minifloppy, the “Twiggy” disk, the 3-inch compact floppy disk, Mitsumi’s “Quick Disk” 3-inch floppies, and Sony’s 3.5-inch disk.

For almost 40 years, the floppy disk ruled the market as an essential way to transfer data or files, but the introduction of new formats such as CDs, USB drives, and other forms of high-speed computer networking and cloud storage in the mid-1990s led to a decline in their popularity. With a modern design and improved storage capacity, the USB “thumb drive” led to the gradual disappearance of the floppy drive. The decline in floppy disk usage became more apparent as computer companies began releasing floppyless computers. A notable example was in 1998, when Apple released the iMac. It didn’t have a slot for floppy disks at all. After the year 2000, floppy disks had almost completely disappeared. Increasingly rare, they are only used with older systems or with legacy industrial computer equipment.

Fossey, Dian (1932–1985)

Dian Fossey was one of the first American primatologists to study gorillas. She was one of the trio of women called the “Trimates” (the other two are Jane Goodall and Biruté Galdikas). Fossey lived with and studied gorillas in their natural habitats. Later, her

goals shifted from research to conservation, because gorilla populations were rapidly declining due to poaching. Her efforts became controversial after she allegedly tortured poachers. In 1985, she was found murdered at her research station.

Fossey was born on January 16, 1932, in San Francisco, California. Her parents divorced when she was six, and her mother was remarried to Richard Price. The Prices hardly ever acknowledged Fossey and oftentimes made her eat dinner alone. She took equestrian lessons and dreamed of becoming a veterinarian, applying for the veterinary program at the University of California, Davis. After failing chemistry and physics courses, Fossey enrolled in the occupational therapy program at San Jose State. Once she graduated in 1954, she moved to Louisville, Kentucky, and worked with polio-stricken children and tuberculosis patients.

In 1963, Fossey took a loan to travel to Africa, where she toured Tanzania and encountered Louis Leakey, the famous anthropologist who studied human origins. Together, they discussed the importance of studying nonhuman primates. She then traveled to Zaire (now the Democratic Republic of the Congo) and met Joan and Alan Root, who were filming a wildlife documentary about mountain gorillas. The Roots invited her to join them. After seeing gorillas for the first time, Fossey was in awe of and felt connected to gorillas.

When she returned home, Fossey wrote about her adventures and published photos in the local paper. In 1966, she met with Leakey again in Louisville. Leakey wanted a protégé to help him research gorillas. Fossey volunteered to study the gorillas, but Leakey told her that she needed to have her appendix removed first. Six weeks later, he wrote to say that he was testing her determination and did not actually require an appendectomy. But Fossey had already had the procedure done. She left for Africa soon after.

Fossey spent 18 years living with and studying the primates in the mountain forests of Rwanda. Fossey built her first research station in the Virunga Mountains of Zaire. Six months later, a civil war broke out, and rebels forced her out of the country. This was a blow, as the gorillas had become familiar to human researchers and photographers. When she relocated to

the other side of the mountains in Rwanda, the gorillas she studied had only met humans as poachers. Her new research station, called Karisoke, became her home for the next two decades.

Fossey earned the gorillas' trust by watching them where they could clearly see her. She learned to imitate their calls and hoots. The younger gorillas would play with her notebooks and pencils while the adults kept guard around her. Fossey recorded everything she saw. She published her research notes in several science journals. With her research and writing, Fossey educated the world about gorillas and how they were gentle giants with complex social behaviors and hierarchies. This culminated in her book *Gorillas in the Mist*, which was later made into a movie.

Over time, Fossey's focus shifted from research to conservation. In the first four months in Rwanda, her research team found 900 hunting traps. Poachers targeted gorillas for the hands and heads of adults, which were to be made into souvenirs and trophies, and they also targeted live babies, who were sent to zoos and individuals around the world. In 1978, one of Fossey's gorilla families was massacred. She buried their bodies next to her research station, and her conservation goals took a dark turn.

Fossey began using extreme techniques to stop poachers. While her writings kept some tourists from buying souvenirs made from gorillas, Fossey terrorized the poachers to keep them out of the mountains. The Rwandans claimed that she taught the gorillas to fear dark-skinned people over whites, kidnapped the child of a poacher who had captured a baby gorilla, and whipped poachers she arrested with stinging nettles.

Fossey's opposition to poachers and tourists eventually led to her murder. On December 27, 1985, she was found dead in her ransacked cabin. The investigation was poorly handled and remains unsolved. Fossey was laid to rest in Karisoke's graveyard, right next to her gorillas. In 1981 the Rwanda gorilla population was under 250 individuals. Today, there are almost 500 gorillas in the Virunga Mountains. Without her research and constant protection, they would most certainly be extinct.

Gates, Bill (1955–)

With the help of Paul Allen (1953–), a longtime friend, William Henry Gates III cofounded Microsoft, a company responsible for developing user-friendly software that revolutionized the computer industry by making it possible for people without technological training to use computers at work and at home.

Gates, who was greatly influenced by his parents, was a gifted student, software designer, and businessman. The success of his company was tied to several factors, including his work ethic, marketing and innovation ability, and strategy. After marrying in 1994 and blocking an antitrust lawsuit against his company in 1998, he retired and devoted his time and fortune to philanthropic endeavors aimed at improving education and eradicating diseases under the banner of the Bill & Melinda Gates Foundation. His philanthropic role was made possible by his work in technology. His optimistic view of the role that technology could play to improve lives has been unshakeable. Gates has received many awards and recognitions for his work.

Gates was born in Seattle, Washington, on October 28, 1955. His father was a successful lawyer, and his mother was a schoolteacher who served as chairperson of United Way International, an organization dedicated to supporting education and health initiatives. Gates developed an interest in computer science in seventh grade at Lakeside School, a private school in Seattle. That year, he met Allen, who shared his interest in computers. While the two teenagers were still in high school, in 1972 they established Traf-On-Data, a temporary firm that used software to determine local traffic patterns. In about a year, the small business had earned them \$20,000. As part of his college application, Gates scored a perfect 800 on the mathematics section of the Standard Aptitude Test (SAT). Although he had developed an interest in computers at

an early age, he chose to study law (like his father) when he enrolled at Harvard in 1973.

At Harvard, Gates accumulated a small fortune as a poker player. Years later, Gates boasted that his success in poker had a lot to do with his ability to calculate mathematical odds. In 1975, Allen dropped out of Washington State University and asked Gates to drop out of Harvard so that they could go into the computer software business together. Gates was convinced after Allen showed him a story in *Popular Mechanics* magazine about the Altair 8800, a \$350 million micro-computer developed in New Mexico by Micro Instrumentation and Telemetry Systems (MITS).

The partners established Microsoft in 1975. Gates paid part of the start-up costs with his poker winnings. Research and development were constant at Microsoft. For about two decades, Gates put in more than 12 hours of work every day of the week (including weekends). It was not until 1994, after he married Melinda French, that he adopted a lighter work week (of a maximum of 12 hours a day during the week and 8 hours a day on weekends).

From 1975 to 1980, Microsoft had moderate success by developing programs for Commodore and Apple business computers. A major focus of the company was the development of Beginner's All-Purpose Symbolic Instruction Code (BASIC), an early programming language. In 1980, Microsoft got its first big break when International Business Machines (IBM) asked Gates for help with its attempt to develop a better personal computer (PC). In response, Gates created the Microsoft Disk Operating System (MS-DOS), which used a text command line interface.

By 1984, MS-DOS had sold more than 2 million copies, making it the world's leading operating system. By the end of the decade, it had sold more than 100 million copies. In 1987, Gates unveiled Windows, which used both a text and a graphic (icon) user interface. He followed it up with the Microsoft Network (MSN) in 1994, Windows 95 in 1995, and Windows 98 in 1998. Windows 98 sold more than half a million copies in the first three days after its release. By 1998, Gates had become the world's wealthiest self-made man.

Marketing played a major part in Microsoft's tremendous success in the 1990s. Microsoft was able to

ensure a steady income stream with advertising that informed consumers of the improved features and greater functionality of each new computer system. Therefore, even though many people had computers, they kept buying newer ones. Another major factor that contributed to Microsoft's success was constant innovation in computer software. For example, in 1997, Microsoft entered the multimedia market with CD-ROMs. Within a couple of years, CD-ROMS with various programs (including games) flooded the market. To promote future sales of CD-ROMS, Microsoft designed them with exclusive compatibility to certain operating systems. Therefore, when consumers purchased newer computers with the latest operating systems, older CD-ROMS became obsolete.

Another reason for Microsoft's success had to do with strategy. Since most computers were equipped with a Microsoft operating system, Gates bundled Microsoft software packages (including word-processing and spreadsheet software) on computer desktops. In an attempt to corner the new Internet market, Gates also bundled each Windows 95 and 98 computer desktop with Microsoft Web browsers. He made Internet access deals with America Online (AOL), Intel, TCI Broadband, Time Warner, and Road Runner.

Many competitors complained that Microsoft had gained a monopoly in the computer and Internet businesses. In 1995, the U.S. Department of Justice blocked Microsoft's attempt to purchase Intuit (a personal finance software company). In 1998, the Department of Justice (along with 18 state attorney generals) filed an antitrust lawsuit against Microsoft. In 1999, a judge for the U.S. States District Court of Columbia, Thomas Penfield Jackson, ruled that Microsoft was, in fact, a monopoly. The ruling made it possible for a multitude of competitors to sue Microsoft for damages. It even made it possible for the U.S. government to break up Microsoft into smaller, less dominant companies. However, the power of the ruling soon eroded, because Jackson's comments to the press (calling Gates an unethical businessman) cast doubt on the judge's impartiality. The U.S. Court of Appeals upheld that Microsoft was a monopoly by a unanimous vote, but it ruled that a new judge would have to decide Microsoft's penalty. However, Microsoft lawyers were able to block a penalty from being issued by

offering to settle the case instead. After two years of negotiations, Microsoft lawyers struck a deal with the Justice Department. The 2001 settlement did little to change Microsoft's great influence in the computer and Internet industries.

In 2000, Gates remained on as Microsoft's chairman, but he stepped down as CEO. He vowed to give away 95 percent of his wealth to charity. Through the Bill & Melinda Gates Foundation, he chose (like his mother) to focus on ways to improve education and combat world diseases. In the field of education, the foundation was committed to donating billions of dollars to support initiatives in public schools and colleges. Two of its greatest areas of focus were helping poor minority groups and improving teacher training, even though skeptics questioned the power of money to save schools. In 2003 alone, the foundation donated more than \$35 million to the Program for Appropriate Technology in Health (PATH) to fight encephalitis. By 2010, the foundation had donated more than \$13 billion in global health grants. However, some critics charged that the foundation lacked a satisfactory way to gauge the effectiveness of its donations. Other critics contested the way that its health grants were awarded. For example, in 2010, a team of researchers at University College London reported that the foundation's donation trends lacked a transparent peer review process. In spite of the criticisms, Gates remained optimistic. He was aware of how computer and Internet technologies could be used to enhance education. He was also aware that technological breakthroughs had the potential to improve world health. In short, Gates possessed a faith in the power of technological innovation to help humanity overcome problems, including illiteracy, poverty, and disease.

Gates wrote two books: *The Road Ahead* (1995), which summarized the implications of the PC and the Internet on the present and the future, and *Business & the Speed of Thought* (1999), which described the modern reality of the integration of business and technology. Gates has been the subject of several documentaries, including the television miniseries *The Machine That Changed the World* (1990). His story has also been told in feature films including *Pirates of Silicon Valley* (1999) and *Steve Jobs vs. Bill Gates: The Competition to Control the Personal Computer*,

1974–1999 (2015). He has been the recipient of many awards, including the U.S. National Medal of Technology (1993) and New York's Institute of Technology's President's Medal of Leadership Award (1995). In 2004, he was given the rare honor for an American of being named Knight Commander of the Order of the British Empire for his service to technology. *Time* magazine named Gates one of the most influential people of the 20th century.

Genetic Engineering

Humans have been altering the genetics of organisms for over 30,000 years by domesticating animals and plants through selective breeding. In the past few decades, the direct DNA alteration of an organism's genome using modern biotechnology has had many useful applications in agriculture, medicine, and scientific research. Scientists have genetically engineered bacteria to synthesize human insulin, among other medical and technological breakthroughs. The most popular controversial application of genetic engineering among the public is, perhaps, the manipulation of food production. Genetically modified organisms (GMOs) and genetically modified (GM) foods have many beneficial possibilities, but they also raise some concerns.

The principle on which genetic engineering is founded is that genetic information, encoded by DNA and arranged in the form of genes, is a resource that can be controlled in several ways to achieve goals in

both pure and applied science and medicine. The term “selective breeding,” coined by Charles Darwin (1809–1882), is the process of selecting organisms with the most desirable or advantageous traits and mating them with the aim of furthering these traits in their offspring. Early humans had no concept of genetics; however, they were still able to cause significant genetic changes to a species by repeatedly choosing selected traits. For example, wild wolves in East Asia were domesticated and selected to increase obedience. Over thousands of years, descendants of these wild wolves were selected for their body shape, temperament, behavior, size, hair length, and color, giving us what we know today as the dog. There are hundreds of dog breeds recognized by the World Canine Organization, yet they all belong to the same species: *Canis lupus familiaris*. Whereas natural selection occurs naturally, selective breeding is referred to as “artificial selection” due to human intervention.

Ten thousand years ago, corn did not exist; there was only teosinte—several wild species native to Mesoamerica. Teosinte was artificially selected by ancient Mesoamericans and is the major component of what evolved to become corn, or maize. The ancient Sumerians and Egyptians used yeast to brew wine and to bake bread as early as 4000 BC. Many ancient civilizations exploited tiny organisms that live in the earth by rotating crops in the field to increase crop yields. People in Mesopotamia used bacteria to convert wine into vinegar. The Greeks used crop rotation to maximize crop yield and also practiced various methods of food preservation such as drying, smoking, curing, salting, etc. All these techniques and processes were practiced in the Middle East and South East Asia, including ancient India.

Biotechnology, according to the U.S. National Science Academy, is the “controlled use of biological agents like cells or cellular components for beneficial use.” Before the 21st century, the term “biotechnology” referred to traditional activities such as making dairy products, wine, bread, beer, etc. For example, the fermentation done in food preparation, by which living organisms such as bacteria or yeast are employed to make useful products, can be considered “classical biotechnology.” Modern biotechnology is similar to

classical biotechnology but differs in technique. The technological advancements of the 20th century in the fields of chemistry, biology, physics, engineering, information technology, and computer application have resulted in modern biotechnology.

In 1906, biotechnology took a leap forward when Gregor Johann Mendel, a part-time schoolteacher and Augustinian monk, announced the findings of his experiments. Using statistical methods in biology for the first time, Mendel established the laws of heredity. He predicted the existence of genes that only recombined and did not change their identity from one generation to another. Derived from the term “genesis,” which relates to the beginnings of things, the science of genetics seeks to understand how organizations both differ from and resemble their parents. Every gene is thought to correspond directly to a specific trait.

By the 1920s, the study of genetics was instrumental in assisting plant breeders to develop improved crops. By the 1940s, agriculture had been transformed by genetics, and the Green Revolution of the 1960s was thus made possible. The discovery of DNA, the material that stores hereditary information in cells, revolutionized the science of genetics. Friedrich Miescher had discovered the chemical DNA in 1869, but it was not accepted as the chemical basis of genes until the early 1950s. In 1953, Rosalind Franklin, Francis Crick, and James Watson discovered the double-helix structure of DNA: two strands were twisted around each other like spiral staircases with bars instead of steps. The structure, function, and composition of DNA are virtually identical in all living organisms. The precise ordering of the chemical base in the DNA molecule is what makes each creature unique. This gave scientists the idea of changing the ordering of chemical bases and so to modify life-forms. H. Gobind Khorana and Marshall Nirenberg carried out the deciphering of the genetic code in 1961.

Between 1972 and 1973, U.S. biochemists Stanley Cohen and Herbert Boyer developed a technique that allowed pieces of DNA to be cut in specific places and attached to the DNA of a target organism. They were the first to directly transfer DNA from one organism to another. The possibility of inserting a human gene into a bacteria and mass-producing the gene led

to the biotechnology revolution. In 1975, the Asilomar Conference on Recombinant DNA was where the first safety regulations for biotechnology were laid out. In 1976, Herbert Boyer formed the first genetic engineering company, Gentech, with the aim of genetically modifying bacteria to produce human insulin. In 1978, Hamilton Smith, Daniel Nathans, and Werner Arber were awarded for discovering enzymes that act like biological scissors, an important tool used in modern genetic engineering.

The 1980s marked the discovery of DNA fingerprinting, a genetically engineered vaccine for hepatitis B, the creation of GM foods, and the rise of the anti-biotechnology movement. Jeremy Rifkin was an anti-biotechnology activist who was against the awarding of the first patent for genetically modified bacteria to Boyer and Cohen. In 1983, Stephen Lindow received the approval to release the first GM bacteria into the environment. In 1988, the entire human genome was planned to be mapped, which was eventually completed in 2000.

Genetic engineering requires a scientist to perform the successful completion of a series of five steps using modern biotechnology. Scientists must first extract the DNA of a desired organism. For instance, if the goal is to improve the nutrition of rice to include more vitamin A, then a gene is added to increase biosynthesis of beta-carotene, a precursor of vitamin A. The second step of genetic engineering involves gene cloning, which is done to separate the gene of interest from other genes, to make thousands copies of the gene of interest, and to transfer it to the target organism.

Copies of genes are made by polymerase chain reaction (PCR), a technique that revolutionized genetic engineering in 1985. When a gene has been cloned, scientists design the gene to function inside a different organism by cutting the gene apart with enzymes and by replacing the sticky ends that have been separated. The gene of interest is inserted into plasmids, tiny circles of bacterial DNA. Using the plasmids carrying the gene of interest, a culture of bacterial cells is infected. The bacterial cells that have successfully acquired the plasmid containing the gene are grown as a pure cell culture. A culture is a clone of identical cells. Each

different clone possesses a different gene. From the many clones, the specific clone containing the gene of interest is selected. There are many different ways to transfer genes, each with their unique challenges depending on the type of cells. Upon successful gene transfer, a genetically modified organism has been created.

GM foods have stirred controversy on the basis of health or environmental concerns. As public awareness of GM foods has increased, many countries have enforced mandatory labeling laws for GM food. Many of the advocacy groups argue that labeling GM food is necessary for consumer choice. However, groups that oppose labels argue that a law would eliminate consumer demand for GM crops, cause sharp increases in resource utilization, and raise food prices. The debate over GM foods is still active as the public has become more aware. The scientific community has largely come together and concluded that the consumption of GM foods is no more dangerous than eating traditionally selected crops. However, there is evidence suggesting potential environmental impacts of GMOs.

The field of genetic engineering is rapidly developing each year with promising biotechnology systems such as CRISPR. In June 2012, researchers targeted the CRISPR system toward specific DNA sequences, showing its potential for genome editing. In January 2013, CRISPR was used on human and mouse cells. In March 2015, there was a report of the first CRISPR gene drive that could spread rapidly through a population. In April 2015, researchers reported that they edited human embryos with CRISPR. Unlike other gene-editing methods, CRISPR is relatively easy to use and quick. CRISPR can potentially accelerate the gene therapy field, making it possible to cure genetic diseases; however, some scientists fear that the accelerated development of CRISPR may leave little time to address safety and ethical concerns. James Wilson, a medical geneticist of the University of Pennsylvania in Philadelphia, has stated that the CRISPR field is still young, and it could be years before its potential is realized.

Gosling, James (1955–)

James Gosling was born on May 19, 1955, near Calgary, Canada. He is considered to be the father of the programming language Java. Even in his early years, Gosling was interested in science. While he was at the University of Calgary, he worked on a project that took data off tapes and created photographs of the Isis 2 satellite from them. While working on this, Gosling also became the local maintainer of TECO, a text editor.

Around the age of 15 or 16, Gosling created a small interpreter while working on a data analysis program. Gosling originally created this program out of frustration after many of his colleagues asked him repeatedly to make the program do several actions. He received a bachelor of science degree in 1977 for computer science from Carnegie-Mellon University, and he received his PhD in computer science in 1983. While working on his doctorate, he wrote a text editing software called Gosling Emacs and developed several electronic mail systems.

Before beginning his career at Sun Microsystems, Gosling had already created a version of *Emacs*, a text editor. However, he renamed his version *Gosmacs*. He created the Java language in 1995, plus the original compiler and virtual machine. Gosling spent a large

part of his career at Sun Microsystems—from 1984 to 2010. In 2010, Gosling encountered issues in the company where he had become a vice president and fellow; Sun Microsystems had recently been obtained by Oracle Corporation, another computer technology corporation. After this change came a legal case in which Google was accused of infringing on Oracle's patents.

Gosling has received honorary awards such as The Economist Innovation Award in 2002 and IEEE's John von Neumann Medal in 2014. He was made a fellow of the Association for Computing Machinery in 2013 and Officer of the Order of Canada in 2007. As of 2017, Gosling began working for Liquid Robotics as its chief software architect. He had written software for an autonomous oceangoing robot in 2011. Gosling has also written a number of books that pertain to his Java program, some of the most notable being *The Java Programming Language* and *The Java Language Specification*.

The Java program has had a large impact on the world of science because of its accessibility. His efforts have helped make building applications and platforms easy for computer users. Java applications are very flexible and can run on any machine. The program is also considered accessible because it is open source. Many people in the professional world and the general public have benefited from Gosling's innovations.

IBM Personal Computer

In 1981, IBM released the first microcomputer designed for personal, individual use. By 1982, the IBM PC had taken the personal computer market by storm and was the microcomputer that set the precedent for all future personal computers. At the end of 1982, IBM was selling one unit for every three in a business day. This wildfire of success set the precedent for desktop computers made for personal rather than business use, establishing a new standard of what a computer was in the eyes of the public.

Before IBM's entry into the personal computer market, the scene was quite small. In fact, Apple may have been the only major player during that time with its then relatively successful Apple II personal computer. IBM had been trying for years to break into that

market with no luck, and after many attempts to create a profitable working prototype failed, many people in IBM believed that creating a personal computer in-house was not possible. There was much opposition when there was talk in IBM about finally designing a personal computer in 1980.

Why did it again try something that many had proven expensive and unprofitable? Just one year prior, IBM did something out of the ordinary and outsourced the processor for one of its experimental computers, the "Datamaster." Traditionally, IBM used processors designed in-house. But it now saw the benefits of outsourcing from Intel: its processors were much more powerful. IBM was then able to design the IBM 5150 personal computer, the model that would set the precedent for future personal computers.

The IBM AT (Advanced Technology) model personal computer was the second-generation IBM personal computer. It became available to the public in 1984. (Bettmann/Getty Images)

After developing the “Datamaster,” IBM outsourced other computer components. IBM CEO Frank Carey encouraged the idea of making a personal computer that was as open in architecture as possible. By August 1980, more than 500 engineers, programmers, planners, marketers, and managers were assigned to the IBM 5150 model project, again using Intel processors. IBM was now familiar with the chipset, and Intel was willing to cut a good deal.

The operating system (OS) for the IBM 5150 was outsourced from Microsoft. Microsoft’s MS-DOS operating system already had professionally published manuals on how to develop software for it, and IBM wanted to encourage third-party developers. The company also marketed its own programs. In a press release on August 12, 1981, IBM vice president C. B. Rogers Jr. said, “We intend the IBM Personal Computer to be the most useful system of its kind. Besides making it easy to set up and operate, we are offering a program library that we expect will grow with the creativity of the personal computer users.” This was very important for the success of the IBM personal computer because at the time, businesses were the main purchasers of computers, and their main motivation to buy them was to use business-focused software like *VisiCalc*.

The Apple II was IBM’s main competitor. Businesses bought the IBM 5150 because of its software, including a program that stored text for editing and printing, as well as video games like *Microsoft Adventure*, where players explored caves in search of treasure. IBM marketed the 5150 as the first computer truly designed for personal, individual use. IBM constrained the proportions of the model 5150 to fit on a desk. This parameter was very important; it set the standard for how computers would look in the future.

The IBM personal computer was seemingly an overnight success. Businesses everywhere were excited about its open-endedness. Over its five-year life span, the IBM 5150 sold about 3 million units—about 2.75 million more than the company had predicted. In one month alone in 1984, it sold about 250,000 units.

The IBM personal computer set the standard for obtaining components and software from several sources that we follow today. Although there are many

computer brands now, they all use processors from Intel and AMD and graphics cards from NVidia. The ability to handle a very large array of software is essential in personal computers today, from the Microsoft Office suite to current commercial video games.

Infant Formula

Infant formula is a powdered substitute for breast milk for feeding infants. Pediatricians generally advise exclusively breastfeeding for the first 12 months of an infant’s life; however, the pace of modern life means that many infants are formula fed today, at least in part, in their first months of life.

For years, researchers have studied the possible benefits of certain fatty acids naturally delivered to babies through breast milk. They tested added fatty acids in infant formula such as DHA (omega-3) and AA (omega-6). DHA and AA are long-chain fatty acids and constituents of fats and lipids. DHA and AA are vital to normal human physiology; they influence membrane “traffic.” The molecules of these particular fatty acids are long chains of lipid-carboxylic acid found in fats, oils, and cell membranes as a component of phospholipids and glycolipids. Fatty acids that are added to infant formula come from animals, most often cows, and vegetable fats and oils. Essential fatty acids are polyunsaturated fatty acids that are synthesized by plants but not the human body and are therefore a dietary requirement.

Numerous studies have compared the red blood cell fatty acid profiles of breastfed and formula-fed

infants and have found that supplementation of infant formulas with DHA and AA results in red blood cell fatty acid profiles extremely similar to those of breast-fed infants and receive the same benefits. It is important to supplement with both DHA and AA, as providing one but not the other produces a state of imbalance.

Although breastfeeding is best for an infant because it contains the perfect amount of antibodies, water, carbohydrates, fat, protein, vitamins, and minerals, some mothers cannot produce milk, or their busy lives prevent them from feeding a newborn. Mothers who cannot breastfeed their babies choose infant formula as their second option. It is important for infant formula to contain the proper ingredients and nutrients (and for parents to know what these are); otherwise, it could be fatal for the infant. Nowadays, infant formula is better at matching the ingredients and proportions of human milk, and infant mortality rates have decreased drastically in recent decades.

Insulin Pump

The NASA-inspired insulin pump is one of the greatest examples of innovation from space technology transferred to the medical field. The insulin pump is a small device about the size of a wallet and contains insulin. The pump has buttons and a screen used to monitor and program how much and when to administer the insulin. The pump has improved the lives of millions of patients who suffer from diabetes.

The earliest insulin pump was invented by Dr. Arnold Kadish in 1963. It was roughly the size of a backpack, however, and it was extremely heavy and expensive. In 1976, Dean Kamen invented a portable infusion pump. NASA’s Viking program, which sent space probes to Mars, provided the inspiration for the insulin pump. The probes had fluid control systems to monitor the many fluids that they required to function, and the systems would replenish them when necessary and allowed the probes to deliver liquid into Martian soil to cultivate microorganisms there.

Before the NASA-inspired insulin pump, people with diabetes had to monitor their blood glucose level manually, pricking their fingers and reading their glucose level from the blood sample with a meter. They sometimes had to do this somewhat painful and unsanitary test up to six times a day.

On November 10, 1986, doctors at Johns Hopkins University successfully implanted the new space-age insulin pump underneath the skin of a man’s stomach. This pump was designed to be very long lasting and could be reprogrammed without removal with another surgery. It monitored the patient’s blood glucose level constantly and consistently, saving the patient from having to do it many times a day. The new pump let patients control insulin delivery with the touch of a button and at precise doses. That is difficult to do manually. People could now manage their diabetes better and protect themselves from its many risks.

The insulin pump inspired by NASA technology has since been improved and positively affected the lives of millions who suffer from diabetes. It provides a much safer way for patients to test themselves and administer insulin with a lower risk of infection. What once was a difficult, dangerous, and time-consuming

treatment is now as easy as pressing a few buttons to keep healthy.

Internet

The Internet is a series of computer networks connected together on a global scale. Through this “internetting” of networks of devices worldwide, users can interact with each other no matter where they live or work. The internetting of networks, or “Internet,” started out as research commissioned by the U.S. government in the 1960s to find a way to communicate across computer networks. In response to this, the U.S. Defense Advanced Research Projects Agency (DARPA) was commissioned in the 1970s to investigate techniques and technologies to interlink packet networks.

The concept was then used by Tim Berners-Lee, inventor of the Internet, to create the World Wide Web (WWW) in the late 1980s. This British computer scientist had parents who were among the earliest computer scientists working on the first computer. He graduated from Oxford University in 1976 and immediately found a job as a software engineer for the Conseil Européen pour la Recherche Nucléaire (CERN), which at the time had a large particle physics laboratory in Geneva, Switzerland. It was there that Berners-Lee thought of the World Wide Web as a way to pass along information of all sorts. Due to Berners-Lee’s idea of sharing information at a much faster pace, the Internet and the World Wide Web have become the giant communications tool we know today.

When DARPA initiated the research for interlinking packet networks, its objective was to create a communication protocol that would allow one networked computer to communicate across multiple linked networks. This protocol is known as the TCP/IP Protocol Suite or the “Internet Protocol suite.” The earliest precursor network, called ARPANET, was used by military and regional academic networks to interconnect with other computers.

Berners-Lee used this process of linking computers together to speed up the sharing of information. Working as a software engineer for CERN, he noticed that there was a problem with acquiring information. He noticed that different information was stored on different computers and that multiple log-ins on multiple computers were required just to retrieve and share it. Oftentimes, computers used different programs, making sharing information harder because the operator had to know how to use them all.

Berners-Lee solved the problem by exploiting a database format called hypertext, which displays text on a computer screen that links topics and refers to other texts. Trying to capitalize on this new idea, in March 1989, he submitted his initial proposal, but it was soon rejected. It wasn’t until the 1990s when he redistributed it that his manager at the time, Mike Sendall, accepted the proposal. By the next month, he had written three essential pieces of computer code that we need even today:

- **HTML:** Hypertext Markup Language. The markup (formatting) language for the Web.
- **URI:** Uniform Resource Identifier. A kind of “address” that is unique and used to identify each resource on the Web. It is also commonly called a “URL.”
- **HTTP:** Hypertext Transfer Protocol. Allows for the retrieval of linked resources from across the Web.

In the mid-1990s, the popularity of the Internet grew. Starting from the United States, it spread to the developing world in the late 1990s. Today, the Internet has grown into an all-in-one destination for accessing information of almost any kind, with e-mail, search engines, and streaming video services being used by

more households than Berners-Lee might ever have imagined. The Internet has redefined traditional communication media like mail, the telephone, radio, television, and newspapers, upgrading immediacy and efficiency. In the attempt to find the true potential of the Internet, Berners-Lee made it free for anyone and everyone to access the “Web.”

At the Massachusetts Institute of Technology in 1994, Berners-Lee founded W3C, an organization composed of several companies with the intention of improving the Web by setting standards. This was when Berners-Lee decided to make the Web free for everyone to improve upon and realize its full potential. In 1999, Berners-Lee wrote an autobiography—*Weaving the Web*—about how he came up with the idea. In it, he recounts the events that led him to the creation of the Web, discusses his vision for it, and addresses issues including censorship and privacy, plus his plans for the future of the World Wide Web.

Net neutrality is the principle that Internet service providers must treat all data on the Internet the same—that they cannot discriminate or charge differently by user, content, Web site, platform, application, type of attached equipment, or method of communication. In December 2017, the U.S. Federal Communications Commission voted to repeal the net neutrality order it had issued in 2015.

Jobs, Steve (1955–2011)

Steve Jobs was the CEO of Apple Computer and the innovative creator of the Macintosh computer, the

iPod, the iPhone, and the iPad, devices that have revolutionized the way Americans communicate and interact with information.

Beyond creating products that reoriented the computer and cell phone industries, Jobs revolutionized recorded music through iTunes, which allowed inexpensive online delivery of music as an alternative to piracy and led to the decline of the CD. He played a major role in Pixar’s transformation of the methods for creating animated films, initiated with the Academy Award–winning *Toy Story* in 1995.

In all his projects, he was known as obsessive in his focus on aesthetic design and attention to detail to enhance the user’s experience. Even though he was accused of micromanaging during his lean years, most came to value his outlook as essential to the success of his products. He had a role in everything from the design of packaging to the look of the Apple Store. The Museum of Modern Art holds 25 Apple products in its design collection.

Jobs is credited as the inventor or coinventor in 338 U.S. patents or patent applications. Even though he earned only \$1 a year as Apple CEO, his ownership of Apple and Disney stock gave him an estimated 2010 wealth of \$8.3 billion, causing *Forbes* magazine to list him as the 42nd wealthiest American at the time. Apple’s iPad tablet, now in its third generation, is currently outselling the number of personal computers being sold by any manufacturer; Apple has sold 58 million iPads since they were first introduced in 2010. Revenue from iPad sales and from the iPhone has made Apple “the most valuable company in the world, with a market capitalization of almost half a trillion dollars, well ahead of its nearest rival, Exxon Mobil,” according to a report in the *New York Times* on the occasion of Apple’s introduction of the third version of the iPad on March 7, 2012.

Jobs began his computer career after dropping out of Reed College and quitting a position as a video game designer at Atari, and after travel to India, an experience that contributed to his conversion to Buddhism. He and Steve Wozniak, a school friend and computer engineer, created the first small, accessible, and inexpensive personal computers, the Apple I in 1976 and, three years later, the Apple II. They are

credited with revolutionizing the industry by offering a true user-friendly personal computer.

Selling for \$666.66, Apple I sales totaled \$774,000, but the Apple II increased revenue 700 percent to \$139 million because it offered color graphics, expansion slots, and primarily the ability to run *Visi-Calcul*, the first computer spreadsheet that made the devices so valuable to business. The company went public in 1980 and achieved a market value of \$1.2 billion on the first day of trading. That year, Jobs brought in a marketing expert, John Sculley of Pepsi-Cola, as president.

The Macintosh computer was released to great fanfare in 1984 with a famous Super Bowl commercial that alluded to the George Orwell novel and depicted a female runner who carried a large hammer breaking free of the Big Brother enslavement of the unnamed but implied IBM personal computer. Despite the success of the commercial and the praise of its design, the Macintosh could not compete with IBM, which dominated business computing, because their operating systems were not compatible.

A series of disappointments soured the relationship between Jobs and Sculley, leading Apple's board to relieve Jobs of his operating responsibilities when it reorganized the company in May 1985. Sales of the Macintosh computer, introduced the year before, were very disappointing, far below expectations. The company was facing the first financial loss in its history. Jobs resigned from Apple in September of that year to start a new computer company called NeXT, which was aimed at producing a computer adapted to the special needs of higher education.

He spent the next 12 years at NeXT in what was a period of failed expectations and flawed business decisions. When released to the market in 1988, the computer cost \$6,500, plus another \$2,000 for its printer, compared to the discounted educational price of \$1,000 for a Macintosh. Academic budgets could not afford it, and after selling only 50,000 units in the following seven years, Jobs ended production.

While a commercial disaster, NeXT ended up as a technological success in the design of its UNIX-based software that became the source of the Macintosh's new operating system, Mac OS X. While at NeXT, Jobs also made his very successful investment in Pixar, an initially struggling company that he eventually sold

to Disney for \$7.4 billion. NeXT was sold to Apple in 1996 for \$429 million, and Jobs was brought back to the company as temporary de facto chief and in 1997 formally as chief executive.

The relationship of Jobs and Apple mirrors mythic patterns, from rise to fall to triumphant return. After his return, Jobs also took a company many considered economically moribund, possibility doomed, and made it at the time of his retirement announcement Exxon's competitor for the prestige of being the world's wealthiest corporation. Measured quantitatively by stock value, the final decade of Jobs's leadership had been a phenomenon. In 10 years, he took the value of the company from \$9 a share to \$376 on the day he stepped down. As *Businessweek* noted just hours after Jobs's death, "Apple's stock price has risen more than 9,000 percent since Jobs returned to the company in 1997." Qualitatively, Apple's recent innovations had changed the nature of computing from a machine on a desktop to a device that fits into the palm of a hand.

Jobs's return to the leadership of Apple resulted in innovations that exceeded all expectations. Yet, ironically, at the height of his success and adulation by Apple devotees, he suffered severe medical problems. He had a first surgery for pancreatic cancer in 2004 and a liver transplant in early 2009, debilitations that led him to give up the leadership of his company and resulted in his death.

The details of Jobs's personal life have not been widely known, and he made efforts to maintain privacy. He was born on February 24, 1955, to parents who were, at the time, graduate students at the University of Wisconsin: Joanne Schieble and Abdulfattah "John" Jandali from Syria, who became a professor of political science. They gave him up for adoption before he had a name, and Jobs was unable to discover the details of his biological parentage until he was 27. He was named Steven Paul Jobs by his adoptive parents, Clara and Paul Jobs. His mother worked as an accountant, and his father was a Coast Guard veteran and machinist who introduced Jobs to electronics through experiments in the family garage, the same garage where the Apple computer was created.

Jobs's biological parents did marry after the death of Joanne Schieble's father, who had opposed the marriage. They had a second child, the novelist Mona

Simpson, who took the name of her stepfather, her mother's second husband. Simpson's novel *A Regular Guy* features a character much like Jobs in an unflattering portrait. Yet the siblings became very close and were in frequent contact.

When he was 23, Jobs and Chrisann Brennan, an artist, had a daughter, Lisa, whose parentage he initially denied for seven years. However, she came to live with him as a teenager. He married Laurene Powell on March 18, 1991, and fathered a son and two daughters. They lived in Palo Alto, California.

Jobs has been compared with Thomas A. Edison as an archetypal American inventor, a man whose innovations revolutionized a society. In many ways, that linking is an exaggeration. Edison, in devising the phonograph, a functional electric lightbulb, and the motion picture camera, brought fundamental changes to American and world society—the ability to overcome darkness with electrical illumination and to record and preserve sound and movement. Jobs enhanced existing technologies with results that transformed the ways in which people interact with devices and information and also produced major effects on a number of businesses.

Rather than the link to Edison, a more relevant comparison may be with Microsoft's Bill Gates, a man of the same generation, also born in 1955 and also essential to the computer revolution. The two men and their companies have been considered major competitors by industry watchers. Yet they followed very different business models and lived very different personal lives. Still, their ascendancy made them contrasting heroes and villains to many. Ironically, those roles shifted with the fortunes of their companies: the greater the success, the more the criticism of the man.

In many ways, Gates deserves credit for the ubiquity of the computer in our lives. He organized the development of the operating systems—from MS-DOS to Windows—that made computers more functional and allowed the products of different manufacturers to interact. But those in the field criticized his programs for their cumbersome coding, their propensity to crash, and their vulnerability to viruses. Microsoft was attacked for predatory practices, using its wealth and power to put smaller companies out of business by offering for free what others had to charge

for. Yet it kept accumulating profits by licensing its programs to computer makers through the world, to the point where more than 80 percent of all computers run on Microsoft software.

Apple, on the other hand, created its own hardware as well as operating software that differed greatly from that of Microsoft. A more important difference—except for one brief attempt—was the decision not to license its software to other manufacturers. Those in the field agreed that the Apple system and equipment were more elegant, trouble free, and easier to use. At the same time, Apple computers were more expensive and, more significantly, for many years did not interact smoothly with the great majority of Microsoft-based computers. Apple served a niche market, appealing especially to those who worked in graphic design and layout. But business and education in general found Apple too specialized for adoption.

Microsoft tacitly admitted that Apple technology was superior, developing its own software to emulate Apple features. For example, Apple was the first with a mouse and a graphic user interface (GUI), substituting clicking on an icon for several steps of keyboard combinations. Microsoft devised the first Windows software to compete and since then has kept up with, and in some cases surpassed, the latest Apple features.

It has been the iPod, and then the iPhone and iPad, that converted large numbers of people to Apple believers. They liked the designs, the quality, and the ease of operation. When Apple opened Apple Stores, people flocked to sample the equipment and to be served by a friendly, knowledgeable staff. Those stores have in themselves become models for other retail operations. Apple computers still are a minority of those sold today, just 10 percent of the U.S. market. The company makes most of its profits from iPhones and iPads—for example, selling 20.34 million iPhones and 9.25 million iPads as compared to 3.95 million Macs in the quarter reported in the company's July 19, 2011, report.

In one of his last public appearances as Apple's CEO to announce a pending new operating system for the company's portable devices and its new approach to cloud computing, the iCloud, Jobs predicted the demise of the computer as a dominant force. The cloud, versions of which already were available,

enables people to store music, video, and data files on distant servers rather than personal computers. All of this information is also accessible on multiple portable devices. Again, Apple took the lead in a direction for computing that may result in a fundamentally new way of interaction in the way that the iPod did with recorded music.

But as Apple rose from an orphaned favorite of technological purists to dominance, wealth, and power, attacks on Steve Jobs accelerated. For years, Bill Gates was castigated for his great wealth, excessive mansion, bland personality, and roughshod tactics. But now that the Bill & Melinda Gates Foundation offers grants from the couple's billions to fight disease and further throughout the world, Gates is no longer disdained.

Apple and Jobs exchanged places for the critics, with Jobs seen as domineering for his rigidity in keeping Apple a "closed" company. Its software codes are tightly guarded. Those who revealed photos and details about a found iPhone prototype were sued and lost the case. Apps proposed by the iPhone and iPad are carefully screened before their sales are allowed. Yet, in the days after his death, only the voices of praise for Jobs were heard.

The day Steve Jobs announced that he was stepping down as CEO of Apple on August 25, 2011, David Pogue of the *New York Times* said of him:

His personality made Apple Apple. That's why no other company has ever been able to duplicate Apple's success. Even when Microsoft or Google or Hewlett-Packard tried to mimic Apple's every move, run its designs through the corporate copying machine, they never succeeded. And that's because they never had such a single, razor-focused, deeply opinionated, micromanaging, uncompromising, charismatic, persuasive, mind-blowingly visionary leader.

Pundits immediately asked whether Apple could maintain the same levels of unprecedented inventive and financial success without Jobs's leadership. Jobs died on October 5, 2011, of the pancreatic cancer that had caused him to resign, one day after the company's

first major product announcement without him. The world's broadcast, digital, and print media were immediately overwhelmed with encomiums to the man and his achievements. He was called the best CEO of the past 50—perhaps 100—years by Google chairman Eric Schmidt.

Jobs's list of accomplishments began when he was just 21 with the introduction of the Apple computer, which was followed by the breakthrough Macintosh and more recently the iPod, the iPhone, and the iPad. Joe Nocera of the *New York Times* called them "more than devices. They were objects of lust."

One researcher even argues that iPhones have become objects of love rather than addiction. Martin Lindstrom, an expert on consumer behavior, gave subjects functional magnetic resonance imaging tests to measure their brain activity as they were shown images of products like the iPhone and also religious images such as rosary beads. He found "uncannily similar" brain activity: "In short, the subjects didn't demonstrate the classic brain-based signs of addiction. Instead, they *loved* their iPhones." If Lindstrom is correct, Steve Jobs is responsible for an unprecedented achievement in American life.

Kare, Susan (1954–)

Susan Kare is an artist and graphic designer who started her career with Apple Macintosh. She is responsible for many of the interface elements on the Apple Macintosh in the 1980s.

Kare was born in Ithaca, New York, in 1954. In 1971, Kare graduated from Harriton High School and moved on to Mount Holyoke College and completed a BA in art in 1975. Kare finished school with a PhD in fine arts from New York University in 1978. Once finished with college, she moved to San Francisco and worked in an art museum. Kare has a husband and three sons.

Kare joined Apple Computer in the early 1980s after a friend from high school phoned her about a position. Originally hired to design user interface graphics and fonts, Kare became the creative director for Apple from 1982 to 1985. She designed icons, typefaces, and marketing material for the original Macintosh operating system. Kare created the grabber, the bomb, the lasso, the paint bucket, the Geneva and Chicago typefaces, the command signal, and Clarus the dog (an indicator of pages printing horizontally or vertically). Frequently used icons created by Kare were the Mona Lisa face (indicating a working computer), the happy Mac (a smiling computer greeting users), the trash can, and the clock (letting users know the computer is busy and cannot be used).

In 1985, Susan Kare left Apple and joined Steve Jobs's company NeXT as a designer. Kare began working with clients such as IBM and Microsoft. She would also design several icons as an independent graphic designer and designed a deck of cards for Windows Solitaire. In 2007, Facebook released gifts designed by Karen that could be purchased for a dollar. The gifts were a success on Facebook, causing Kare to create limited edition gifts. In 2015, Kare was hired by Pinterest as a lead product designer. Pinterest planned to assign her tasks such as designing buyable pins, app pins, refined interfaces, and a guided search.

Currently a partner in Susan Kare LLP, Kare is also a cofounder for Glam.com and a creative director for Chumby Industries Inc. Designs of Kare's stationery and notebooks are exhibited in the Museum of Modern Art store in New York City. Kare has her own digital design company in San Francisco, where she sells limited edition signed prints and fine art. Her icons have been used on more than computers. Prints of them have been put on shirts and displayed in the *New York Times Magazine* as well as on paper as art that is hung on walls. Kare's icons have become famous for their ability to communicate their function instantly and memorably, with wit and flair.

Laser Cataract Surgery Device

The Laserphaco Probe is a medical device that ablates and removes cataracts from eye lenses with a laser through a relatively painless process. Originally conceived in 1981, it was later patented in 1988 by the ophthalmologist Patricia Bath, the first African

American female doctor to receive a patent for a medical invention.

Patricia E. Bath was born on November 4, 1942, in Harlem, New York. The daughter of an immigrant from Trinidad and a woman descended from African slaves and Cherokee Native Americans, Patricia grew surrounded by the sexism, racism, and poverty that were often present in Harlem in the 1950s and 1960s. Her parents strongly encouraged her toward an academic career, and when she was just 16, she became one of the few students selected to attend a cancer research symposium promoted by the National Science Foundation. Bath graduated from high school in just two years and then attended Howard University, where she received her medical degree with honors in 1968.

During her early career at the Harlem Hospital, Bath discovered that blindness among African Americans was double that among all other patients. To address this issue, she proposed the development of a new discipline, community ophthalmology, to increase the amount of eye care provided to underserved populations. After joining the faculty of University of California, Los Angeles and Charles R. Drew University in 1974, Bath was the first woman in the United States to be appointed chair of ophthalmology in 1983.

In 1981, she started working on her best-known invention, the Laserphaco Probe, a new method to remove cataracts that was well ahead of its time. In the next five years, she took her research abroad to the Laser Medical Center of Berlin in Germany, where she learned more about laser science. The device was completed in 1986 and later patented on May 17, 1988. The Laserphaco Probe is still used worldwide to restore sight to countless patients and has been substantially improved since its invention. The laser can, in fact, dissolve the cataract by vaporizing it, and it's much more reliable, fast, and accurate than the traditional drill-link devices used in ophthalmic surgery. The Probe also includes a system that irrigates and cleans the eye, and suction tubes to remove the ablated lens material.

In 1993, Bath retired from the UCLA Medical Center and was then the first woman to be appointed to the honorary medical staff. Shortly afterward, she was named a Howard University Pioneer in Academic

Medicine. In May 2001, Bath was also inducted into the International Women in Medicine Hall of Fame. Today, she continues to advocate vision care through telemedicine, using telecommunications technology to provide medical services outreach to remote areas.

Metcalf, Robert (1946–)

Robert Melancton Metcalfe, nicknamed “Bob,” is a world-famous electrical engineer from the United States. His projects have included Ethernet, founding 3Com, and formulating Metcalfe’s Law. He has worked for major technology concerns such as the Massachusetts Institute of Technology (MIT) and Xerox. At Xerox, he developed his most important project, Ethernet, in 1973. In January 2011, he joined the University of Texas at Austin in the position of professor of electrical engineering and director of innovation.

Metcalf was born on April 7, 1946, in Brooklyn, New York, and grew up on Long Island. His father is also an engineering technician. In 1964, he graduated from Bay Shore High School and entered the Massachusetts Institute of Technology (MIT), class of 1968. But he graduated in 1969 with two bachelor of science degrees: one in electrical engineering and the other in industrial management. For his master of science degree, he went to Harvard and majored in applied mathematics, finishing in 1970, and earned his PhD in computer science there in 1973.

While Metcalfe was earning his PhD, he worked at MIT because Harvard refused to let him connect the school network to the ARPANET. Metcalfe’s job was

with MIT's Project MAC, to build hardware that could link all of MIT's minicomputers with ARPANET. After a few failures, he was successful after he read a paper about the ALOHAnet at the University of Hawaii. He fixed the bugs in the ALOHA network, which helped him in his PhD work at Harvard. He then worked at Xerox PARC, where he invented Ethernet with David Boggs.

Computers sent data and signals to modems through Ethernet cables, which converted the signals to analog signals that could be transferred through existing phone wires. This is very similar to how a telegraph machine works. On May 22, 1973, Metcalfe documented the invention of Ethernet. Ethernet initially was for connecting computers over short distances, but it also allows more remote computers to communicate. For example, to download a file from an e-mail account, one computer sends a signal to the other to let it know that a file should be downloaded from its drive to the remote drive. Ethernet lets users send data to each other.

After he documented his invention, Metcalfe, David Boggs, and Tat Lam had built the first Ethernet prototype, which had a maximum speed at 2.94 Mbps. After three years of improvements, Metcalfe and Boggs published "Ethernet: Distributed Packet Switching for Local Computer Networks." In 1978, Xerox invented the X-Wire, which can run up to a 10 megabyte-per-second (Mbps) Ethernet on a coaxial cable.

After all these inventions, Metcalfe founded 3Com to commercialize Ethernet in 1979. In February 1980, the Institute of Electrical and Electronics Engineers (IEEE) started on project 802 to standardize local area networks. Then, Metcalfe asked Gordon Bell, who worked at Digital Equipment Corporation (also known as DEC), David Liddle at Xerox, and Phil Kaufman at Intel to join him to develop Ethernet based on the invention of X-Wire. The group of four experts was called "DIX." After a year of researching, the group published the "Blue Book," which contains Ethernet specifications.

Many computer hardware companies started to produce Ethernet materials and products to the world and to the DIX group for further development. More people were getting into the development of Ethernet.

Grand Junction Networks was founded to develop Fast Ethernet products that could provide high-speed Internet exchanges up to 100 Mbps. In 1998, Ethernet made history and turned 25 years old.

For Metcalfe's success, he was awarded the IEEE Medal of Honor in 1996 for "exemplary and sustained leadership in the development standardization, and commercialization of Ethernet." In May 2007, he was inducted to the National Inventors Hall of Fame in Akron, Ohio, for his invention of Ethernet, which still brings people fast networking today.

Microchip

The microchip is a collection of transistors that is the fundamental building block of all circuits and electronics in use today. These transistors lie arranged on a silicon wafer board. Since there are two possible states of being on a transistor—on and off—the nature of the silicon semiconductor is ideal for this, being able to conduct or block the flow of electricity. Different types of microchips enable the storage of various amounts of data.

The microchip was created as a result of the collaboration between Robert Noyce and electrical engineer Jack Kilby in 1958 at Texas Instruments. This wasn't an easy task. The first obstacle was the

Microchip technology lies at the heart of the computer revolution. Smaller, more powerful microchips have allowed for lighter, faster, and more powerful computers, electronic notebooks, cell phones, watches, and more. (Corel)

difficulty in creating perfect circuits to flawlessly enable the travel of electricity. It was especially difficult because circuits were made manually and soldered by hand. Due to occasional human error, electricity was not always able to traverse the circuit due to faulty connections. Additionally, these circuits had to be as small as possible to provide the speedy travel of electricity; the microchip depended on such speed to be effective.

Kilby made the first step toward the first functioning microchip when he eliminated many of the major obstacles. He is credited with the idea of putting all the necessities for a circuit on the same board. This meant

that people no longer needed to build and connect the components manually. The silicon semiconductor board improved the efficiency and accuracy of the connections.

Soon, Noyce created another functioning microchip whose model followed many of the same principles of production that Kilby's had used. Although Kilby's design had moved all the components onto a single board, they still had to be connected by wires. Noyce improved the design of the chip with a metal sheet placed on top of the circuit board; large areas of the metal sheet were then stripped, leaving behind an intricate layout of metal paths. These paths provided the connections for conducting electricity throughout the board. Noyce's design made widespread mass production of the microchip possible.

Not only did Noyce's design of the microchip change the way the components were laid out, but also, the type of materials used for production were modified. Introducing new materials into the equation allowed Noyce to overcome problems such as incidental electrical shortages within the circuit.

As with any revolutionary invention, a patent must be filed to prevent others from stealing its ideas. The patent was filed on July 30, 1959, and then published on April 25, 1961, just when some major obstacles pertaining to the production of integrated circuits had been overcome. Noyce was inspired to create an insulated surface layer for the semiconductor to adhere to oxide layers. This strengthens the electrical connections to various parts of the conductor without causing shorts between junctions.

The immense demand for microchips today has resulted in much more productive ways of generating enough to fulfill it. Modern microchips are produced layer by layer, in a process where UV light is beamed at photosensitive material over a template of the schematics. Overlapping layers of this material compose the microchip with all the correct connections. This enables mass production with enhanced precision. However, since these microchips are miniscule, even small specks of dust can ruin them. So, workers in the manufacturing of microchips must wear clean suits in clean rooms to prevent contamination. The layers of microchips are transported throughout the lab in air-tight capsules.

Microchips have become very powerful. Cofounder of Intel Gordon Moore has noted in several interviews that the number of transistors in its microchips had doubled every year. This observation is referred to as Moore’s Law. While this figure is massive, it also gives an idea of how rapidly microchip technology has improved. Due to competition and the pursuit of innovation, companies are constantly developing more efficient ways to program microchips. They are smaller but contain more transistors than ever. The microchip is a fundamental piece of technology used today in almost every electrical appliance. We can anticipate that it will continue to improve in efficiency and power.

Microsoft

Microsoft is an American technology corporation that started out writing software for the world’s first PCs with its first product, a programming language called BASIC. It continued to develop software and operating systems, making its products compatible with Internet use. The Windows operating system has been its most successful operating system, and it is used worldwide to this day.

Microsoft began in 1975 when high school friends and eventual cofounders Bill Gates and Paul Allen created and sold their first product. They developed the programming language BASIC for the Altair 8800, which was owned by Micro Instrumentation and Telemetry Systems Inc. (MITS). MITS agreed to distribute the product as Altair BASIC. Gates kept the copyright for the BASIC programming language, and Microsoft continued to develop programming

software for other systems independently from MITS. At the close of 1978, sales were above \$1 million.

Microsoft received its biggest break in 1980 when IBM requested an operating system for its new personal computer aimed at consumers. Gates purchased an operating system and sold it to IBM, calling it “MS-DOS.” It was introduced on IBM’s new personal computer. Microsoft’s collaboration with IBM was a crucial part of the growth of Microsoft. Over 150 million PCs were operating on MS-DOS at that time.

By 1985, Microsoft Windows, a graphical user interface that allowed users to connect with their PCs interactively, was shipped. Windows became the most popular user interface in computer history. Mini applications were also included in the Windows bundle, from *Notepad* to *Windows Paint*. Windows let the user control the computer with a Microsoft Mouse, but an additional innovation in keyboard commands allowed the program to be used by an even broader base of users. In 1986, the company revealed *Microsoft Works*, which had word processing, spreadsheets, databases, and drawing functions all in one program. By 1986, the company went public. In 1989, *Microsoft Office* was announced as spreading to CD-ROM and *Office 1.0* for Macintosh.

The 1990s was the Windows era. Microsoft shipped Windows 3.0 in 1990, and of course it was instantly a number-one seller. This year also marked the company’s 15-year anniversary.

By 1993, the Windows NT release allowed business applications to operate on an open, reliable platform. In 1995, the company released Windows 95 along with a Microsoft Network online service. Windows 95 successfully sold over 1 million copies within four days, and the software is the bestselling in history. The success of Windows 95 helped bring PCs into 250 million homes, businesses, and schools worldwide. That same year, with the growth and spread of the Internet, Microsoft recognized its need to adapt to the changing communication world and added Internet capabilities to all of its products. In 1997, it released Internet Explorer 4.0, which had high customer demand. At the end of the 1990s, Microsoft was making almost \$20 billion in revenue with a high growth rate and over 30,000 employees.

Throughout Microsoft history the company has partnered with unlimited number of other companies and acquired a few along the way as well. To kick off the millennium in the year 2000, Microsoft made its biggest purchase, acquiring Visio Corporation. In the same year, cofounder Gates stepped down from his position as chief executive of Microsoft to take on a new role as chairman and chief architect, becoming more involved in the development of the next-generation Windows Internet platform.

Microsoft continued to grow and flourish, and Windows continued to advance year after year. In 2001, Windows XP was released, followed by Windows Vista, Windows 7, and Windows 8 by 2011. Microsoft also entered the gaming world, introducing the first Xbox game console in 2001. New features and models followed. Soon, Microsoft was competing with international video game companies such as Sony and Nintendo.

The company also launched a Windows phone in 2011, keeping up with changing market demands. In 2008, Gates finally retired from the company, retaining his role as chairman. Most recently, Microsoft has continued to advance into the future with programs for the cloud. In 2016, Microsoft reported revenue reaching \$22.6 billion. The company continues to be a leader in computer software worldwide.

Mobile Phone

First introduced in 1973, mobile phones have become an integral part of contemporary American daily life. The mobile phone has undergone both technological

and dimension advances. From the first Motorola DynaTAC 8000x to the advent of the smartphone, the mobile phone has given us the ability to communicate wirelessly over great distances and has become vital to us.

The first mobile call was made on April 3, 1973, by a group of Motorola engineers led by senior engineer Martin Cooper. He called a rival telecommunications company and informed them he was speaking via mobile phone. It was a decade before Motorola released its first commercially available phone, however—the DynaTAC 8000x. It weighed 1.1 kilograms and measured 228.6 x 127 x 44.4 millimeters. Taking 10 hours to charge, the handset offered 30 minutes of talk time, six hours of standby, and could store up to 30 phone numbers. Early mobile phones were large and generally used in cars. They retailed for a staggering \$3,995. Despite the cost and low talk time, the demand was strong; those on waiting lists numbered in the thousands.

The DynaTAC 8000x mobile phone was launched on the United States' first 1G network by Ameritech. It cost \$100 million to develop and took over a decade to reach the commercial market. However, the first analog cellular system widely deployed in North America was the Advanced Mobile Phone System (AMPS) developed by Bell Labs and activated on October 13, 1983. AMPS suffered several issues compared to modern standards; most glaring was its unencrypted transmission, which was highly susceptible to eavesdropping via a scanner. It was vulnerable to cloning and took a significant amount of bandwidth to support its transmission of data. Many of the iconic early commercial cell phones such as the Motorola DynaTAC Analog AMPS were eventually superseded by Digital AMPS (D-AMPS) in 1990, and AMPS service was shut down by most North American carriers by 2008.

In the 1990s, mobile phones saw a new generation emerge. Two widely utilized networks competed for the ability to transmit data of this second generation of mobile phones: the European-developed GSM standard and the U.S.-developed CDMA standard, both 2G networks. Instead of transmitting data via analog signal, these networks used a more efficient digital signal. Increased efficiency and protection led to a rise in

mobile phone usage. Because of the 2G network, this era saw the advent of prepaid mobile phones.

The development of smaller mobile phones in the 1990s aided in increasing their popularity. The IBM Simon, regarded as the first smartphone, featured a touch screen. On December 3, 1992, Neil Papworth sent the first short message service (SMS) text to Richard Jarvis. It read, “Merry Christmas.” A year later, AT&T introduced the EO Personal Communicator, the first tablet computer with wireless connectivity via mobile phone line. Access to the mobile Web was a major improvement for mobile phones in the 1990s. The first access to the mobile Web was commercially offered on the Nokia Communicator 9000 and has been present on nearly all phones since.

Between 2000 and 2003, the mobile phone saw two of the biggest changes in its physical configuration. The BlackBerry 5810 made the QWERTY keyboard a popular standard, and the arrival of LCD touch screens revolutionized how users interacted with data. The smartphone as we know it today was invented. Smartphones could now download software programs known as “apps.” Several models included calendars, Web browsers, and Bluetooth capabilities, along with a host of other built-in features. The Motorola Razr V3 featured a sleek, thin design. One of the premier folding phones became Motorola’s bestselling phone ever, at more than 130 million between 2004 and 2006.

With 2G broadband growing in popularity, people began to use their phones daily, increasing demand for faster data transmission speeds. The 2G broadband could not handle the needed speeds; therefore, developers began working on a 3G network. The main difference between the two was the use of packet switching versus circuit switching. In 2007, there were 295 million 3G users around the world.

In 2008, the Apple iPhone 3G was introduced, widely considered the phone with the single biggest impact on the industry. The iPhone combined the iPod’s ability to store and play music with the wireless communication of mobile phones. It introduced people to the app store concept and made touch screens the norm.

It was clear by 2009 that the explosion of streaming media and other bandwidth-intensive applications would soon overwhelm 3G networks. The industry

thus started to develop data-optimized fourth-generation technologies, which promised a 10-fold speed increase over existing 3G technologies. The WiMAX standard (offered in the United States by Sprint) and the LTE standard (offered in Scandinavia by TeliaSonera) became the first two commercially available technologies to be billed as 4G.

4G differed technologically from 3G in its elimination of circuit switching, employing instead an all-IP network. 4G treated voice calls just like any other type of streaming audio media; it used packet switching over Internet, LAN, or WAN networks via VoIP. The main improvement with 4G over 3G technology was the ability to transmit data up to 10 times the speed of its predecessor.

With the ever-growing demand on mobile networks, coupled with technological advancements, there’s no limitation on the capabilities of future devices. Mobile phones now have access to GPS functions, which allow the phone to tell users where they are and where they want to be; Web-browsing capability; and e-book reading. Mobile phones can also be used as music listening devices, flashlights, calculators, and much, much more. The ability to send and receive information at a moment’s notice makes the mobile phone an invaluable asset in today’s society.

Nuclear Energy/Nuclear Power Plants

Nuclear energy is any method of doing work that makes use of nuclear fission or fusion reactions. Nuclear energy refers to the controlled release of energy, such

as in a nuclear power plant. A nuclear power plant is a power station that has a heat source that is a nuclear reactor. The heat is used to generate steam that goes in a turbine connected to an electric generator, which produces electricity. Nuclear energy is regarded as a practical, inexpensive, and clean (emissions-free) source of energy. Today's nuclear energy production saves around 24 billion tons of carbon dioxide emissions per year that would otherwise be caused by coal-fired power generation. Fuel is a small part of the cost of producing electricity, but it is uncertain how much is spent on fuel management.

The world's first exposure to nuclear power first came when two atomic bombs were exploded over Nagasaki, Japan, and Hiroshima, Japan, in August 1945. After World War II, a number of scientists looked to harness the power of nuclear energy to perform work. They soon realized that it was difficult to get the energy they wanted. In fact, they only managed to produce a modest degree of energy from their attempts.

The first nuclear reactor was built during World War II as part of the Manhattan Project to build an atomic bomb. It was built as the first concrete test of existing theories of nuclear fission. It consisted of alternating layers of uranium and uranium oxide with graphite as a moderator or reactor core. Cadmium control rods were used to control the concentration of neutrons in the reactor. The moment that the control rods were withdrawn can be regarded as the beginning of the age of controlled nuclear power in human history.

Every power plant contains four fundamental elements: the reactor, the coolant system, the electrical power-generating unit, and the safety system. The reactor initiates and controls a sustained nuclear chain reaction. The coolant captures and transfers the heat released by fission in the nuclear reactor for use in electricity generation. The coolant also maintains manageable pressure within the core. The electrical power-generating unit converts the heat from fission to electrical energy. The amount of electricity that a nuclear reactor or power plant generates depends on the amount of time it operates at a specific capacity. For example, the Fort Calhoun plant in Nebraska has one reactor with the smallest generating capacity of

479 megawatts (MW). If the Fort Calhoun reactor operates at full capacity of 479 megawatts (MW) for 24 hours, it will generate 11,496 megawatt-hours (MWh) of power. Most power plants do not operate at full capacity every hour of every day of the year.

Constructing a modern nuclear power plant has a high cost, mainly due to the enormous range of safety features needed to protect against various possible mishaps. Every nuclear plant is required to have an elaborate safety system to protect against the most serious potential problem of all: the loss of coolant. This would result in the reactor core melting down and releasing radioactive material to the rest of the power plant. This must be avoided at all costs.

There are debates about the safety of nuclear power. Although nuclear energy is dangerous, several government agencies create and implement procedures to ensure the safety of people and the power plants. Still, unforeseen accidents can occur, such as the nuclear disaster in Fukushima, Japan, in spite of all the safety systems developed by nuclear engineers. The general public has long had serious concerns about the use of such plants as sources of electricity. The Fukushima event was caused by a 9.2 earthquake, which caused a tsunami that disabled the power supply and cooling of three Fukushima Daiichi reactors, causing a nuclear accident on March 11, 2011. The concern about nuclear power plants and the public fear of the technology might have arisen due to the world's first exposure to nuclear power: atomic bomb blasts that began in the 1940s.

One of the most troubling issues for nuclear power plants is waste management. After a time, the fuel rods in a reactor can no longer sustain a chain reaction and must be removed. These rods are highly radioactive and pose a threat to human life and the environment. Techniques must be developed for the destruction and/or storage of these wastes. At the moment, the U.S. government has decided to construct a huge crypt in Yucca Mountain in Nevada for the burial of high-level waste. This is only a temporary solution and needs to be improved.

Still, nuclear power plants play a vital role in energy generation. While they may be dangerous, several safety procedures are put in place, and the amount of clean energy they produce is what makes nuclear

energy so rewarding compared to other clean energy options. Scientists and nonscientists alike express hope that fusion reactions can someday be harnessed as a source of energy for everyday needs. This, however, has been much less successful compared to fission power plants.

Open-Source Software

Open-source software (OSS) is software with source code that any person can inspect, modify, and enhance for free. “Source code” is the part of software that most computer users don’t ever see; it’s the code that computer programmers write and can then manipulate to change how programs and applications work.

By design, open-source software licenses promote collaboration and sharing because they permit many people to view the code, copy it, learn from it, alter it, or share it. They encourage computer programmers to access, view, and modify open-source software whenever they like, as long as they let others do the same with their work when they share it. In general, open-source licenses grant computer users permission to use open-source software for any purpose they wish. Some open-source licenses stipulate that anyone who releases a modified open-source program must also release the source-code for that program alongside it.

In contrast, some other software has source code that only the person, team, or organization who

created it—and maintains exclusive control over it—can modify. This is “closed source” software, and it includes software such as Microsoft Office and Adobe Photoshop.

Many users prefer open-source software to closed-source software for a number of reasons. First, programmers have more control over open-source software. They can examine the code to make sure it’s not doing anything they do not want it to do, and they can change parts of it that they don’t like. Users who aren’t programmers also benefit from open-source software, because they can use it for any purpose they wish, unconstrained by the developer’s intentions. And it is often free to use.

Second, people who are interested in programming like open-source software because it trains them and helps them become better programmers. Because open source code is publicly accessible, students can easily study it as they learn to make better software. Students can also share their work with others, inviting comment and critique as they develop their skills. When people discover mistakes in programs’ source code, they can share those mistakes with others to help them avoid making the same mistakes themselves.

The third reason that people prefer open-source software is security. Because anyone can view and modify it, someone might spot and correct errors or omissions that a program’s original authors might have missed. And because so many programmers can work on a piece of open-source software without asking for permission from original authors, they can fix, update, and upgrade it more quickly than they can closed-source software.

Last, open-source software is stable. Users often prefer it to closed-source software for important, long-term projects. Because programmers publicly distribute the source code for open-source software, users relying on it for critical tasks can be sure their tools will not disappear or fall into disrepair if their original creators stop working on them. Additionally, open-source software tends to both incorporate and operate according to knowable standards.

While most of the Internet was born and has grown thanks to Linux open-source software, technology giants such as Google, Apple, and Facebook have embraced the open-source movement. In September

2015, Google made TensorFlow, the artificial intelligence (AI) software powering its search engines, available to the public to play with and improve. In December 2015, Apple made Swift—its own coding language—open source too. Facebook has now open-sourced almost 400 projects and has hundreds of thousands of followers on GitHub. All of these reflect a fundamental shift: to the acknowledgment of a more decentralized model of development for software.

As the digital world grows more complex, it becomes more difficult to manipulate the mountains of data and tasks. Open-source software proves to be an efficient solution by making its source code available to others so that it is developed, tested, or improved through public collaboration and distributed with the idea that it must be shared with others, ensuring an open future collaboration.

Perlman, Radia (1951–)

Radia Perlman is an engineer and mathematician who invented Spanning Tree Protocol, or STP. Spanning Tree Protocol solved an information-routing problem that was integral to the foundations of the Internet. For her invention, Perlman became known as the “Mother of the Internet.”

Born in 1952 in Virginia, Perlman grew up in New Jersey. While studying at the Massachusetts Institute of Technology, she undertook an undergraduate research opportunity with the LOGO Lab called Toddler’s Own Recursive Turtle Interpreter System (“TORTIS”). The project enabled children as young as

three and a half years old to program educational robots and made Perlman a pioneer of teaching young children computer programming.

After obtaining her master’s degree in mathematics in 1976, Perlman accepted a position with Bolt Beranek and Newman in government contracting to develop software for network equipment. Her work on network routing attracted the attention of the Digital Equipment Corporation (DEC), which she joined in 1980. Perlman was tasked with working on ways for computers to reliably share information. Her research led to the invention of Spanning Tree Protocol in 1985, which allows a network to deliver data reliably by making it possible to design the network with redundant links. This method enables automatic backup paths if an active link fails, and it disables the links that are not part of the tree—thereby creating a single, active path between any pair of network nodes. The first version of Spanning Tree Protocol was based on Perlman’s algorithm, called DEC STP, and subsequent versions have incorporated various extensions. Spanning Tree Protocol transformed the original limited-scalability, single-wire CSMA/CD into a protocol that could handle large clouds. As a result, the basic traffic rules for large networks, like the Internet, were laid. The concept was adopted by the IEEE as a standard for bridge technology and remains in place to this day.

Perlman obtained her doctorate in computer science from the Massachusetts Institute of Technology in 1988, with a thesis on routing in environments where malicious network failures are present. Her thesis served as the basis for much of the work that now exists in the field. She also holds an honorary doctorate from the Royal Institute of Technology. In 1997, she joined Sun Microsystems, where in 2007, she was given the title of distinguished engineer. She continues her work in network security today, working to make STP more robust and stable while establishing optimal paths between points as part of the transparent interconnection of lots of links (TRILL) project. Perlman has also served as a professor at Harvard University, the University of Washington, and the Massachusetts Institute of Technology. She has authored numerous textbooks on networking and network security and holds more than 100 issued patents. She has also

received numerous awards, including the first-ever Anita Borg Institute Women of Vision Award for Innovation (2005), the USENIX Lifetime Achievement Award (2006), and the SIGCOMM Award (2010). She was inducted into the Internet Hall of Fame in 2014 and the National Inventors Hall of Fame in 2016.

Personal Computer (PC)

While engineers might look to an earlier date for the birth of the personal computer, for business historians, it was 1977 that launched its mass merchandising. Today, the year is known as the “1977 Trinity” of Apple, Radio Shack, and Commodore computers. This trinity brought monitors, keyboards, and tape (as in the standard cassette tape of the period) memory to the previous mathematical boxes and video games. In 1977, Radio Shack offered the first mass-marketed PC in the TRS-80, with prices starting at \$600. Radio Shack proved that the personal computer would be a mainstream consumer product. The Commodore PET was also released in 1977 with a price of \$800; and while it had limited success, it would set the stage for the highest-selling sales model ever, the Commodore 60, a few years later. Commodore would be the first to use major retail store outlets such as Kmart. Similarly, the limited release of the Apple II would herald the beginning of the personal-computing giant Apple Inc. The Apple II had a price between \$1,200 and \$2,600, depending on its memory size. Apple chose to develop its own retail outlets. The TRS-80 sold through Radio Shack would set the business sales model for many companies, while the Apple II would set the consumer

design model for mass merchandising the personal computer.

The commercial history of the personal computer can be traced to the 1975 release of the Altair computer kit in *Popular Electronics*. The Altair kit cost around \$400 and was little more than a box with switches. While the Altair with the Intel 8080 chip delivered little, it did spark a burst of creativity in the marketplace. One incubator of this creativity was the Homebrew Computer Club near Stanford University.

Apple founders Steve Jobs and Steve Wozniak, future founders of Apple Computer, were members of this hobbyist group. Wozniak tested out his ideas for the Apple computer at the Homebrew Club. Jobs, his partner, injected the business and marketing assets into personal computer design. Wozniak worked hard to reduce the chips needed for a personal computer from over 50 to just 5. The Apple II had a monitor for graphical display, which was lacking in the Altair. Out of the trinity of personal computers in 1977, the Apple II was the first to use a color monitor. From the start, Jobs incorporated his vision of “user friendliness” that would come to characterize Apple products. The team of Jobs and Wozniak proved the perfect balance of technology and business sense. Apple II was the best customer-oriented product with a ready-to-use computer out of the box. Apple II sales started off slow, lacking the mass marketing of larger companies, but proved the impact of word of mouth in the consumer base among hobbyists and gamers.

The Radio Shack TSR-80 was the first personal computer produced by a major company, which was Tandy Corporation, owner of 3,000 retail stores and a national mailing list. Tandy used its engineering staff to hold down costs, realizing that the market would be price sensitive. Tandy Corporation tried to move beyond electronics hobbyists by offering software applications on cassette tape. It gave blackjack and backgammon software away for free and offered additional applications, such as for personal finance and small business payroll management. Tandy’s marketing had identified a market potential of the personal computer in small businesses. Tandy’s marketing pushed sales over 10,000 in the first two months.

The Commodore PET (Personal Electronic Transactor) was aimed at educators and calculator users of

the time. Commodore's experience was in calculators. In the early 1970s, there was a brisk market in programmable calculators sold by Texas Instruments, Hewlett-Packard, and Commodore. These programmable calculators sold for around \$800 but were popular with engineers and educators. The PET's price of \$800 made it very competitive in the calculator market. It had a tough, single-unit design (monitor, processor, and keyboard) that made it popular with schools, in which Commodore's marketing group had inroads. The calculator-based keyboard, however, limited its general popularity. The Commodore PET never matched the sales of the TRS-80 or Apple II, but it did set the platform for the Commodore 64, which addressed its market shortcomings. In the 1980s, the Commodore 64 sold through outlets like Kmart and made it the Model T of personal computers—and the world's bestselling personal computer model of all time. Commodore proved that the personal computer could be a mass-produced consumer product.

The trinity of personal computers with their various business models would evolve into a huge consumer market combining hobbyists, gamers, engineers, small businesspeople, scientists, and educators. Two developments during the next two years would expand the market and sales of the personal computer. The first was the use of floppy drives versus the slow standard cassette drives. IBM had invented floppy drives in 1967, and hobbyists were using them with their Altairs. A floppy drive could read 100,000 bits per second versus a mere 1,000 bits per second for a cassette drive. Floppy drives allowed a market to develop in software applications. Cassette storage had limited the personal computer to small, simple programs. The next development would be to release a breakthrough application. The trinity of personal computers still attracted people who were proficient in writing programs.

The limited applications available for small businesses and professionals were restricting the market. Interestingly, software became a separate industry as initially, companies like Apple focused on hardware. Still, to a large degree, the lack of software was the limiting factor in early hardware sales. The breakthrough application was *VisiCalc*, a spreadsheet

application for accounting and financial calculations. Daniel Bricklin and Robert Frankston developed it on an Apple II computer. They began selling the application for \$200, and the software became the driving force for Apple sales, which boomed. The company's stock went public in December 1980. Still, the major adoption of personal computers in the business world would await the introduction of the IBM personal computer in early 1982.

Ride, Sally (1951–2012)

Physicist Sally Kristen Ride was the first American female astronaut to go to space. She was also the first lesbian astronaut and held the record for being the youngest astronaut from the United States to have been launched into space. She spent her last years encouraging children, especially girls, to do well in math and sciences by creating Sally Ride Science.

Ride was born in Los Angeles, California, on May 26, 1951. She was a good student overall but liked science best. Ride was also an exceptional athlete and excelled at tennis; she subsequently was a nationally

Sally Ride, seen here on Day 6 of her 1983 *Challenger* mission, was the United States' first woman in space. (National Archives)

ranked junior tennis player and earned a tennis scholarship to the Westlake School for Girls. She attended Swarthmore College and the University of California, Los Angeles before graduating from Stanford University with a bachelor of arts in English and a bachelor of science in physics in 1973. Ride continued her studies at Stanford and earned a master of science in 1975 and a doctorate in 1978, both in physics.

Like many young Americans, Ride was fascinated with space exploration, but in the 1970s, the National Aeronautics and Space Administration (NASA) only hired male ex-military test pilots for its astronaut program. But in 1978, Ride saw a NASA recruitment

advertisement in the Stanford University newspaper that asked for scientists for the Space Shuttle program. The announcement did not exclude women. Ride applied for a position as a NASA scientist and was among 35 people out of 8,000 applicants to be chosen for the program.

Ride trained for over a year and then qualified to be a mission specialist for the space shuttle flight crews. She served on the ground crew for two shuttle launches and helped design the shuttle's robotic arm. In 1982, she married Steven Hawley, who was also a NASA astronaut. The couple divorced five years later. In 1983, on the *Challenger's* second launch, Ride became the

first American woman in space (two Soviet women preceded Ride). Her first mission was the STS-7 mission for satellite deployment and microgravity research. She was launched into space in 1984 for a second time on the space shuttle *Challenger* for the STS-41-G mission for satellite deployment and radar imaging. Ride orbited Earth for approximately 344 hours total. In 1986 when the *Challenger* exploded in midair, killing all the astronauts aboard, Ride's next mission, which was supposed to take place aboard the *Challenger*, was canceled, and she was called to serve as part of the presidential commission to investigate the accident.

After the investigation, Ride worked at NASA for a few more years until she became a professor of physics at the University of California, San Diego in 1989. That year, Ride also became the director of the California Space Institute and then founded Sally Ride Science in 2001 to motivate girls to pursue careers in STEM (science, technology, engineering, and mathematics) programs with business and life partner Tam O'Shaughnessy. The company's mission is to create science projects aimed at attracting children and teenagers, particularly girls, to science. Ride was also the company's president and CEO and positively influenced the education system with her advocacy of science to young girls. Using her English degree to further educate the public, Ride wrote books with O'Shaughnessy about science and space exploration, including six well-regarded children's books.

A few years later in 2003, Ride was appointed to be a member for the space shuttle *Columbia* investigation team when it disintegrated upon reentry into Earth's atmosphere, killing everyone on board. She was the only person to have served on both committees for the disasters of the *Challenger* and *Columbia* space shuttles.

Ride received many awards, including the Von Braun Award, the NASA Space Flight Medal (twice), and the General James E. Hill Lifetime Space Achievement Award, among others. Ride was diagnosed with pancreatic cancer in 2011 and died in 2012. She continues to receive awards and honors even after her death. In 2013, President Barack Obama presented O'Shaughnessy with the Presidential Medal of Freedom (the highest civilian award in the United States), who accepted it on behalf of her partner, Ride.

Ritchie, Dennis (1941–2011)

Dennis Ritchie was a very accomplished computer scientist who considered himself not smart enough for physics and complex algorithms. Ritchie's most notable contribution to the world of computing was the creation of the C programming language. He built it by adding "types" and other features onto the B programming language between 1969 and 1973, much like what Bjarne Stroustrup would do with the C++ programming language in the coming years. Ritchie developed his C language in parallel with the Unix operating system, which he aided Ken Thompson in building during their employment at Bell Labs in Murray Hill, New Jersey. The C programming language became a far greater success than he had anticipated. Ritchie owes much of the language's success to Thompson, who had developed the B programming language, and Martin Richard, who had developed B's predecessor BCLP.

Born in Bronxville, New York, on September 9, 1941, Dennis Ritchie was the son of Alistair E. Ritchie, who himself had coauthored a highly influential book with W. Keister and S. Washburn called *The Design of Switching Circuits* focusing on switching theory and logic design before the advent of the transistor. Ritchie started working at Bell Labs, following in his father's footsteps in 1967, and soon thereafter began contributing to the Multics (Multiplexed Information and Computing Service) project, a collaborative effort between Bell Labs, the Massachusetts Institute of Technology, and General Electric to create a time-shared operating system.

Ritchie began development on the C programming language in 1969, and its development peaked

in 1972 before he completed the base language in 1973. His original desire was to create a programming language that incorporated many of the advanced features from the Multics (Multiplexed Information and Computing Service) operating system. These features were to include an explicit notion of a process as a locus of control, a tree-structured file system, a command interpreter as a user-level program, simple representation of text files, and generalized access to devices. Even more features were to be added in 1977 and 1979 when the Unix operating system began flexing its ability to be highly portable, but it was not until the mid-1980s that the language would be standardized by the American National Standards Institute X3J11 committee.

The C programming language was originally designed to be the foundation for the Unix operating system but has since grown to be the most widely used programming language in every industry today and can be used with most platforms. Ritchie, along with Brian Kernighan, coauthored and published the second edition of *The C Programming Language* in 1988 under Prentice Hall Inc. The book has seen great success and countless translations, and it is still one of the most popular programming references today. Ritchie had other interests in computer science as well, including cryptography, which he spent some time researching and discussing with the National Security Agency, and computer games, which he collaborated on with Thompson.

Ritchie had a very diverse life that included many distinct interests and life experiences, including a brief truck-driving career where he was quickly promoted to safety director for the Swift Transportation company. He also worked as a driver hauling NASCAR race cars to and from races for the Roush Racing and Valvoline team. After spending some time on his high school audio and video squad, Ritchie delved into a

small side career as a recording engineer for up-and-coming country and western singers in Nashville, Tennessee. Among these artists was the prominent Jill Anne Curington as well as some less lucrative artists from Brazil. These alternative careers were short-lived compared to his lifelong career in computer science.

Ritchie was the recipient of numerous prestigious awards, including the Association for Computing Machinery's award for Outstanding Paper of 1974 in systems and languages, the Institute of Electrical and Electronics Engineers Emmanuel R. Piore Award in 1982, a Bell Laboratories Fellowship along with the Association for Computing Machinery's Turing Award and Software Systems Award in 1983, the C & C Foundation Award of NEC in 1989, and the Institute of Electrical and Electronics Engineers Hamming Medal in 1990. In 1988, Ritchie was elected to the U.S. Academy of Engineering, and 11 years later, in April 1999, Ritchie was presented the U.S. National Medal of Technology by president Bill Clinton. Dennis Ritchie passed away in early October 2011.

Primary Document: Abstract for "The Development of the C Language" by Dennis Ritchie (1993)

In this abstract of his paper on "The Development of the C Language," Dennis Ritchie discusses the history of the development of the C programming

language. The full paper touches on the language's predecessors such as B and BCPL and the origin of the language in terms of what he was trying to

accomplish. Much of the focus is on the problems that occurred during its creation, how he solved these problems, and what became of the C programming language after its inception. He also touches on the C++ language, C's successor, and the standardization of C as the most commonly used programming language, which he credits to the success and widespread usage of the Unix operating system developed by Ken Thompson and himself.

The Development of the C Language by Dennis M. Ritchie

ABSTRACT

History: the setting

The late 1960s were a turbulent era for computer systems research at Bell Telephone Laboratories. The company was pulling out of the Multics project [Organick 75], which had started as a joint venture of MIT, General Electric, and Bell Labs; by 1969, Bell Labs management, and even the researchers, came to believe that the promises of Multics could be fulfilled only too late and too expensively. Even before the GE-645 Multics machine was removed from the premises, an informal group, led primarily by Ken Thompson, had begun investigating alternatives.

Thompson wanted to create a comfortable computing environment constructed according to his own design, using whatever means were available. His plans, it is evident in retrospect, incorporated many of the innovative aspects of Multics, including an explicit notion of a process as a locus of control, a tree-structured file system, a command interpreter as user-level program, simple representation of text files, and generalized access to devices. They excluded others, such as unified access to memory and to files. At the start, moreover, he and the rest of us deferred another pioneering (though not original) element of Multics, namely writing almost exclusively in a higher-level language. PL/I, the implementation language of Multics, was not much to our tastes, but we were also using other languages, including BCPL, and we regretted losing the

advantages of writing programs in a language above the level of assembler, such as ease of writing and clarity of understanding. At the time we did not put much weight on portability; interest in this arose later.

Thompson was faced with a hardware environment cramped and spartan even for the time: the DEC PDP-7 on which he started in 1968 was a machine with 8K 18-bit words of memory and no software useful to him. While wanting to use a higher-level language, he wrote the original Unix system in PDP-7 assembler. At the start, he did not even program on the PDP-7 itself, but instead used a set of macros for the GEMAP assembler on a GE-635 machine. A postprocessor generated a paper tape readable by the PDP-7.

These tapes were carried from the GE machine to the PDP-7 for testing until a primitive Unix kernel, an editor, an assembler, a simple shell (command interpreter), and a few utilities (like the Unix rm, cat, cp commands) were completed. After this point, the operating system was self-supporting: programs could be written and tested without resort to paper tape, and development continued on the PDP-7 itself.

Thompson's PDP-7 assembler outdid even DEC's in simplicity; it evaluated expressions and emitted the corresponding bits. There were no libraries, no loader or link editor: the entire source of a program was presented to the assembler, and the output file with a fixed name that emerged was directly executable. (This name, a.out, explains a bit of Unix etymology; it is the output of the assembler. Even after the system gained a linker and a means of specifying another name explicitly, it was retained as the default executable result of a compilation.) Not long after Unix first ran on the PDP-7, in 1969, Doug McIlroy created the new system's first higher-level language: an implementation of McClure's TMG [McClure 65]. TMG is a language for writing compilers (more generally, TransMoGrifiers) in a top-down, recursive-descent style that combines context-free syntax notation with procedural elements. McIlroy and Bob Morris had used TMG to write the early PL/I compiler for Multics.

Challenged by McIlroy's feat in reproducing TMG, Thompson decided that Unix possibly it had not even been named yet needed a system programming

language. After a rapidly scuttled attempt at Fortran, he created instead a language of his own, which he called B. B can be thought of as C without types; more accurately, it is BCPL squeezed into 8K bytes of memory and filtered through Thompson's brain. Its name most probably represents a contraction of BCPL, though an alternate theory holds that it derives from Bon [Thompson 69], an unrelated language

created by Thompson during the Multics days. Bon in turn was named either after his wife Bonnie, or (according to an encyclopedia quotation in its manual), after a religion whose rituals involve the murmuring of magic formulas.

Robotic Surgery

Robotic surgery is a relatively new area of technology. The earliest known procedure involving robotic assistance was in 1985, where the PUMA 560, a surgical arm, assisted in a neurosurgical biopsy. Since then, technology has come a long way. 1990 marked the first time a system, created by AESOP, of this type was approved by the U.S. Food and Drug Administration for use, but it was not until 2000 that the FDA approved the first surgery system as we know it today. The da Vinci Surgical System, made by the current powerhouse of the industry, Intuitive Surgical, allows for extreme precision, reduced chance of infection, and reduced scarring. Robotic surgery has been praised for its smooth and fluid movements, which exceed those of even the most precise human being.

Robotic surgery is not without controversy. As with any new technology, it is expensive. With robots ranging in price upward of \$1 million, procedures that use robotic assistance often cost more than those completed by human physicians. Another critique of adopting robotic assistants as the norm is that it requires additional surgical training, which puts an even greater burden on surgeons who are already bogged down by years of schooling. Additionally, since the only way to learn these procedures is hands on, and the number of robotic surgery devices is limited, operating rooms often become backed up with procedures. It can take 12 to 18 operations before a surgeon adapts to the robotic surgical assistant. The American Congress of Obstetricians and Gynecologists opposed robotic surgery, as it did not feel there was yet a significant-enough depth of evidence that

the pros of reduced recovery time outweighed the extra burden taken on by hospitals and patients alike due to the high costs.

However, if the burdens of cost can be put aside, examples of the advancements in robotic surgery bring hope to those who wish to maintain a normal life despite the need for extreme surgeries. In the short term, some patients have been able to leave the hospital just days after major surgery due to the lack of invasiveness on the part of the robots. The lack of deep incisions at the hands of a surgeon means that patients are less likely to reopen a wound soon after an operation, and they can return to daily activity more easily. Additionally, while it is still disputed, robotic-assisted surgery's greater precision appears to lower mortality rates of procedures in both the short term and the long term.

Primary Document: Letter from Elizabeth A. Kage, Acting District Director of the FDA, to Gary S. Guthart, President of Intuitive Surgical Inc., on the Regulation of Robotic Surgery (2013)

This letter between Elizabeth A. Kage, acting district director of the FDA, and Gary S. Guthart, president of Intuitive Surgical Inc., reflects the ongoing regulations of robotic surgery so that it meets acceptable standards for the maintenance of human life. Intuitive, the company largely responsible for the development and production of the “da Vinci” system, the premier surgical assistant device, was found to have mislabeled devices, and it was told to create a report on why this happened. This is important historically for understanding the development and restriction on the usage of these devices while they are being sold for profit by businesses that are responsible for the health of the general population.

Mr. Guthart

During an inspection of your facility located at 1266 Kifer Road, Sunnyvale, CA between April 1, 2013 and May 30, 2013, and investigator from the United States Food and Drug Administration (FDA) determined that your firm manufactures computer controlled endoscopic surgical systems and associated accessories. Under section 201(h) of the Federal Food, Drug, and Cosmetic Act (the Act), 21 U.S.C. § 321(h), these products are devices because they are intended for use in the diagnosis of disease or other conditions or in the cure, mitigation, treatment, or prevention of disease, or to affect the structure or any function of the body.

The inspection revealed that your da Vinci System IS1000, da Vinci System IS1200, da Vinci System IS2000, da Vinci System IS3000, Tip Cover Accessory, and Cannula 8mm Regular are misbranded devices under section 502(t)(2) of the Act, 21 U.S.C. 352(t)(2), in that you failed or refused to furnish material or information respecting the device that is required by or under section 519 of the Act, 21 U.S.C. § 360i, and 21 CFR 806-Medical Devices; Reports of Corrections and Removals regulation. Significant deviations include, but are not limited to the following:

Failure to submit a written report to FDA within 10 working days of any correction or removal of a

device if the correction or removal was initiated to reduce the risk to health posed by the device or to remedy a violation of the act which may present a risk to health as required by 21 CFR 806.10(b).

Examples of these failures include but are not limited to the following:

1. In October 2011, Intuitive Surgical, Inc. initiated a field correction by sending letters to da Vinci Surgical System clients with suggestions and recommendations for the proper use of the Tip Cover Accessory and for the correct generators that should be used with monopolar instruments. This correction was in response to complaints and medical device reports (MDRs) for arcing through damaged tip covers that caused patient injuries. Though the field action was undertaken to reduce a risk to health posed by the device, you failed to report the field action to the FDA as required. Your report of this recall on April 19, 2013 has been classified by FDA as a Class II recall, Z-1425-2013.
2. In October 2011, Intuitive Surgical, Inc. initiated a separate field correction by sending letters to da Vinci Surgical System clients to notify them that the da Vinci Surgical Systems promoted for thyroidectomy indications is not cleared for that use. You are aware of complaints and MDRs related to thyroidectomies performed with the da Vinci Surgical System. Though the field action was undertaken to reduce a risk to health posed by the device, you failed to report the field action to the FDA as required. Your report of this recall on April 19, 2013 has been classified by FDA as a Class II recall, Z-1426-2013.
3. In October 2011, intuitive Surgical, Inc. initiated a separate field correction by sending letters to da Vinci Surgical System clients with information for inspecting the instrument cannulas, proper flushing of the instruments, and proper transportation of the da Vinci Surgical System between buildings. Though the field action was undertaken to reduce a risk to health posed by the device, you failed to report the field action to

the FDA as required. Your report of this recall on April 19, 2013 has been classified by FDA as a Class II recall, Z-1428-2013.

4. In January 2013, Intuitive Surgical, Inc. initiated a field correction by sending letters and replacement user manual addendum titled “da Vinci, da Vinci S, and da Vinci Si Surgical Systems User Manual Addendum for Transoral Surgery (TORS) P/N 552003-02 Rev.B 2012.09” to da Vinci Surgical System clients. The replacement addendum includes changes to the types of patients and conditions for which da Vinci TORS is indicated, such as warning against use in pediatric patients. Though the field action was undertaken to reduce a risk to health posed by the device, you failed to report the field action to the FDA as required. Your report of this recall on April 19, 2013 has been classified by FDA as a Class II recall, Z-1424-2013.

We have reviewed your response dated June 7, 2013 and find it incomplete and inadequate. Your standard operating procedure titled Field Actions, document 853012, revision T indicates that all corrections, removals, and labeling reiterations will be reviewed with the local district recall coordinator or 3rd party expert. We are unable to assess the adequacy of this change as we cannot evaluate the extent of the information that will be submitted to the local FDA recall coordinator. Nor can we assess how you will implement this new requirement in your SOP.

In addition, Section 6.3 of your work instruction titled Regulatory Notifications, document 859179, revision F intended to be used after a determination is made to file a field correction/removal indicates that Class I and Class II actions are to be reported, and Class III actions will be directed to the Head of Regulatory Affairs. This work instruction appears to contradict your Field Actions SOP, document 853012, which indicates that all corrections, removals, and labeling reiterations will be reviewed with the local district recall coordinator or 3rd party expert.

The FDA has previously informed you of your firm’s correction and removal violations in an untitled letter dated February 19, 2008, and FDA 483 Inspectional Observations issued on December 20, 2002.

A follow-up inspection will be required to assure that your corrections and/or corrective actions are adequate and properly implemented.

The inspection also revealed that your da Vinci System IS1000, da Vinci System IS1200, da Vinci System IS2000, da Vinci System IS3000, Tip Cover Accessory, and Cannula 8mm Regular are adulterated devices under section 501(h) of the Act, 21 U.S.C. 351(h), in that the methods used in, or the facilities or controls used for its manufacture, packing, storage, or installation are not in conformity with the Current Good Manufacturing Practice (CGMP) requirements for devices which are set forth in the Quality System regulation, as specified in Title 21, Code of Federal Regulations (CFR), Part 820. Significant deviations include, but are not limited to the following:

Design input requirements were not adequately documented as required by 21 CFR 820.30(c). Specifically, you informed our investigator that you are aware of patient injuries associated with intraoperative cleaning of energized instruments such as the Monopolar Curved Scissors and Fenestrated Bipolar Scissors as evidenced by at least (b)(4) complaints and 82 MDRs during calendar years 2010 and 2011, and 15% of the MDRs reviewed by our investigator. You also informed our investigator that you are aware that cleaning instruments inside patients during surgery is a common practice and have included a label warning in the Instructions-for-Use (IFU) against the practice. When our investigator asked you to provide the design input documentation and design resolution of this known user need you failed to provide the requested documentation.

We have received your response dated June 7, 2013 and find your response to this observation inadequate. Your modification to section 8.1 of document number 823033, revision H in that you are concluding that the IFU adequately consider the known intraoperative cleaning of instruments and the associated risks without going through your design control processes. Your response is also inadequate in that you do not provide a response to the root cause of this critical missing design input in your design documentation.

Your firm should take prompt action to correct the violations addressed in this letter. Failure to promptly correct these violations may result in regulatory

action being initiated by the FDA without further notice. These actions include, but are not limited to, seizure, injunction, and/or civil money penalties. Also, federal agencies may be advised of the issuance of Warning Letters about devices so that they may take this information into account when considering the awarding of contracts.

Please notify this office in writing within fifteen business days from the date you receive this letter of the specific steps your firm has taken to correct the noted violations, as well as an explanation of how your firm plans to prevent these violations, or similar violations, from occurring again. Include documentation of the corrections and/or corrective actions (including any systemic corrective actions) that your firm has taken. If your firm's planned corrections and/or corrective actions will occur over time, please include a timetable for implementation of those activities. If corrections and/or corrective actions cannot be completed within fifteen business days, state the reason for the delay and the time within which these activities will be completed. Your firm's response should be comprehensive and address all violations included in this Warning Letter.

Your firm's response should be sent to: Lawton W. Lum, Director of Compliance, 1431 Harbor Bay

Parkway, Alameda, CA 94502. Refer to the Unique Identification Number 406661 when replying. If you have any questions about the contents of this letter, please contact: Compliance Officer Sergio Chavez at 510-337-6886.

Finally, you should know that this letter is not intended to be an all-inclusive list of the violations at your firm's facility. It is your firm's responsibility to ensure compliance with applicable laws and regulations administered by FDA. The specific violations noted in this letter and in the Inspectional Observations, FDA 483, issued at the close of the inspection may be symptomatic of serious problems in your firm's manufacturing and quality management systems. Your firm should investigate and determine the causes of the violations, and take prompt actions to correct the violations and bring the products into compliance.

Sincerely,
/S/
Elizabeth A. Kage
Acting District Director

Satellite Radio

Satellite radios are radios that receive signals from satellites that move in space at the same speed as the rotation of the earth. These satellites are stationary in space and follow the earth's orbit, so satellite radios in homes have a stronger signal compared to radios serviced by terrestrial antennas. Satellite signals are broadcast nationwide as signals are sent from Earth to the satellite and then transmitted back to Earth, with much wider coverage than terrestrial radio stations. Terrestrial radio consists of antennas that are placed near the radio station to broadcast the signal over the air to a local area only.

In 1988, XM Satellite Radio was invented by Hugh Panero and Gary Parsons, who wanted to bring satellite and online radio broadcasts to the United States and Canada. On May 17, 1990, Martine A.

Rothblatt, Robert Briskman, and David Margolese developed Sirius Satellite Radio, which was a satellite and online radio service that operated in North America. Officially launching on September 25, 2001, it was not until July 29, 2008, that XM Satellite Radio and Sirius Satellite Radio merged to create Sirius XM Radio, as satellite radio is known today in the United States, and its affiliate, Sirius XM Canada, began its service in 2010. The Astra satellite service currently operates in Europe, with other countries' satellite services not currently operational.

The company known today as Sirius XM Radio has more than 18 million paying subscribers. They can listen to Sirius XM Radio on their phones, in their cars, or in their homes. Satellite radio uses two Boeing HS 702 communication satellites nicknamed "Rock" and "Roll," and two Boeing BSS 702 communication satellites called "Rhythm" and "Blues." These Sirius

XM Radio satellites are in a stationary orbit, or a geosynchronous orbit, that is parallel to Earth, with two of the satellites at 85 degrees west longitude, and the other two satellites at 115 degrees west longitude. The radio receivers on the ground are meant to unscramble and receive digital data to provide more than 170 radio channels for Sirius XM subscribers.

These satellite radios have become progressively more popular over the last 10 years as subscribers admire the range and different genres of uncensored content and music, like country and hip-hop, talk, comedy, and even local weather, sports, and traffic. One of the many positives that subscribers enjoy when listening to Sirius XM Radio is the lack of commercials, since subscriber fees pay for the service. While many listeners of Sirius XM Radio enjoy listening to radio in their homes, these subscribers enjoy using Sirius XM Radio in their cars because of the wide broadcast range that Sirius XM Radio provides throughout North America as they travel through different counties or states where terrestrial radio signals cannot reach.

Self-Driving Cars

The concept of a self-driving car, or rather, a driverless car, dates back nearly to the inception of the car itself. Just 40 years after the car was created, drivers were already looking for avenues to get their hands off the wheel. The first instance of this came in 1925, offered by Houdina Radio Control. Houdina created the American Wonder, a car that could be controlled

through an antenna with radio waves from a short distance. At the time, it was revolutionary, despite the need for the controller to be traveling just behind the car. But it would not be long before further developments were made. In 1958, RCA had a car running along a track with electrical circuits that ordered it to accelerate, stop, and turn. At one point, in 1960, four states were eyeing construction of a highway link with this kind of circuitry.

The 1980s upped the ante with the Prometheus project, where German engineer Ernst Dickmanns worked with Mercedes-Benz to create a van that could travel at 39 miles per hour. It reacted to sensory input that was translated to commands for the program. American ingenuity entered the modern fray of the self-driving car in 1991, when legislation was passed that asked the Department of Motor Vehicles to create a roadway that was fully automatic. Due to waning funding, however, the project was canceled shortly after a 1997 demonstration in San Diego. Meanwhile, Ernst Dickmanns was furthering his development of a robotic car, helping to drive it through Paris traffic at 20 miles per hour in 1994. By 1995, the car made a trip to Copenhagen from Bavaria, traveling faster than 100 miles per hour.

At the turn of the century, the race for a self-driving car turned away from being a country-led proposition and became one for various international companies to compete for, putting companies like Ford, Mercedes-Benz, BMW, and Audi at the forefront of the picture. Famously, Audi created an autonomous vehicle capable of traversing Pike's Peak, one of the highest summits in the Rocky Mountains. Legislation in 2011 allowed access for driverless vehicles in Nevada on the open road.

Google entered the bidding around this time and began working with several car companies to produce new technology. Google's project came to fruition in 2014 after taking to several roads throughout the country as more states passed legislation allowing these cars. Google had planned to entirely remove the steering wheel and pedals from its car, which had not been done before. Google had the goal to place fully functional models in San Francisco by 2015. While self-driving cars are not available to the public yet, many companies are pressing for their implementation.

Google has aimed for a 2020 offering, while Mercedes has already added some autopilot features to its cars starting as early as 2014.

Ethical questions arise in the event of accidents with driverless cars. If someone were to unknowingly step out in front of a driverless car and was hurt, is the person or the company responsible? Critics offer the idea that a computer does not have the capacity to make an unbiased decision about human life. These questions inquire about whether it is morally acceptable to move forward with this technology.

SEMATECH

Founded in 1987 in Austin, Texas, SEMATECH, short for “semiconductor manufacturing technology,” is a nonprofit consortium that does research for advancements in silicon chip technology and development. The company’s main objective is to procure technologies that reduce manufacturing costs while decreasing the number of defects per chip. This consortium consists of several companies working toward a common goal of producing high-quality, advanced microscopic silicon computer chips, otherwise known as silicon integrated circuits, while retaining a competitive edge as a worldwide leader and innovator in the semiconductor industry.

SEMATECH began as a partnership between the U.S. government and 14 semiconductor chip manufacturers to resolve manufacturing inefficiencies and gain

a competitive edge over Japan, who at the time dominated the industry. The consortium includes industry giants such as Intel and Texas Instruments. An initial five years of funding came from the U.S. Department of Defense at \$100 million per year, which was collectively matched by the partnering companies. Since that time, the organization has been successful at reducing 30 percent of costs associated with research and development (R&D) for each new generation of chip miniaturization and has steadily reduced those R&D costs over time.

SEMATECH has expanded its operations from being a U.S.-only research consortium to include companies and researchers from the international market, helping it in its global initiative to be an innovator in the research and development of semiconductors and microchip technology. SEMATECH is also involved with research at the State University of New York’s College of Nanoscale Science and Engineering (CNSE) in Albany, where it relocated its operations in 2011. The NanoTech Complex there became the organization’s permanent headquarters. The CNSE has invested over \$6.5 billion in its facility, which is 800,000 square feet in size. It also has a computer chip production line as well as clean rooms for the chip manufacturing process.

The organization continues to show a strong presence in the industry and participates in various worldwide conferences; it also hosts workshops. SEMATECH delivers papers, presentations, and joint reports at major industry conferences. SEMATECH conducts research on the technical challenges with a focus on higher productivity, miniaturization, and mass commercialization in developing new materials, processes, and equipment for semiconductor manufacturing. With this approach in mind, it has conducted advanced research in new materials, such as those of nanotechnology. The consortium currently performs research in emerging technologies for device structures, metrology, manufacturing, and environment and safety issues involved with those technologies. SEMATECH continues its work at the CNSE while it develops programs in lithography and metrology.

The success of SEMATECH’s partnership with the government is a model of how the private and public sector can collaborate with manufacturing industries to either restore an industry or jump-start a new

sector. The success of this partnership has had an immense effect on the U.S. economy. From the companies that produce the equipment to those that manufacture the chips to unrelated companies that use the chips in their products, most of the success of smaller and more affordable technologies has largely been a result of the success of the chip manufacturing industry. This had a domino effect branching out into other technological fields and paving the way for several innovations, giving rise to innumerable successful technologies and companies associated with them.

Solar Energy

Solar energy is a newer, revolutionary form of renewable energy in which light energy from the sun is captured and converted to solar power, which can then be used to power many everyday needs. The earth receives enough sunlight to meet our current and growing energy demands, and solar energy is becoming increasingly popular as we strive to avoid the use of fossil fuels and natural gas. This renewable energy source is an ideal technology to decrease dependence on nonrenewable sources, as it does not pollute nearly as much, and there is a never-ending supply of sunlight.

There are many different technologies involved in solar energy, such as photovoltaic systems, solar water heating, and solar architecture. These structures are designed to get the most energy from the sun as possible. Some combine technologies such as active solar panels and photovoltaic systems. These technologies can be categorized as either active or passive solar; the definition is based upon how the technologies harness and convert heat and light from the sun to solar power.

When sunlight reaches the earth, the intensity of the radiation is actually quite low, and therefore, collectors need a large surface area to capture as much radiation as possible and convert it to either thermal energy or electrical energy. The most common active solar collectors for capturing solar energy are called “flat plate” collectors. These are widely used to heat homes and for hot water. Flat plate collectors generally consist of a black metal plate that is covered by several layers of glass that are heated by the sun’s rays. The heat produced is then transferred to carrier fluids, which are simply air or water, to assist in the solar energy conversion process. The heat that this system provides can be used directly, or it may be stored for later use, such as during cloudy periods or at night when sunlight is not present and energy isn’t being made. These flat plate collectors are efficient in the 20 to 80 percent range, depending on design.

Photovoltaic cells, or solar cells, are another technology used in solar energy, but they convert solar radiation directly into electricity. Albert Einstein, known for his work on the theory of relativity, was the first to define the photoelectric effect in 1906 and 1907, and this paved the way to understanding solar energy. In these cells, light hits the area between two semiconductors and generates a small electric voltage. Although cells don’t produce much power individually, connecting them to create “solar panel arrays” can generate hundreds of thousands of kilowatts of electric power.

Unfortunately, the efficiency of photovoltaic cells is still fairly low, at only about 15 to 20 percent. Their low efficiency, combined with their high cost to produce a moderate amount of power, leads photovoltaic cells to be used mainly in low-power situations, such as for calculators and watches.

Passive solar energy technologies and techniques are a bit different from active solar ones. In passive solar, no external devices are used; this technology takes advantage of its local climate and surroundings to get the most power possible. Passive solar is often involved in the design of structures, as is the case with solar architecture. This practice involves cool roofs or green roofs, and radiant barriers. When constructing buildings incorporating passive solar architecture, engineers and architects take the local environment into account and may align the building to be directly

These Solar Energy Generating Systems (SEGS) in the Mojave Desert use a parabolic trough system to generate solar power. As of 2018, solar power accounts for 30 percent of grid demands, while wind power makes up another 10 percent. (iStockPhoto.com)

in the sun's path to ensure that a large amount of energy can be harnessed. This practice takes into account latitude, altitude, and cloud cover, along with many other factors, to maximize the overall efficiency without breaking the bank.

Solar energy has been around for decades now, but this technology did not take off as it should have until recently. Again, the earth receives enough sunlight in a day to more than power our needs. The main reason it has taken us so long to adopt solar energy technologies is that, although solar energy provided from the sun is “free,” the technology and devices to convert its rays into usable solar power are still fairly expensive. The purchasing and installation of solar panels can cost homeowners tens of thousands of dollars. Although the government often offers tax reductions for homeowners with solar and the power generated has the potential to lower electricity bills, the initial start-up costs for solar energy

are too high for many. Until we can find a way to make these technologies more affordable and readily available for everyone, we will still depend greatly on nonrenewable sources such as petroleum, biofuel, and fossil fuels.

Space Shuttle

The space shuttle was the first reusable spacecraft in history. Created by the National Aeronautics and Space Administration (NASA) and made possible with a diverse team of thousands of civil servants and industrial contractors, the shuttle program lasted from 1981 to 2011. The five space shuttles—*Columbia*, *Challenger*, *Discovery*, *Atlantis*, and *Endeavor*—had a total of 135 launches. Two critical in-flight failures of the *Challenger* and *Columbia* orbiters caused the deaths of 14 astronauts. Nevertheless, the space shuttle was responsible for the deployment of significant satellites and interplanetary probes. It was a principle ferry in the construction of the International Space Station and enabled the dramatic deployment and in-flight repair of the Hubble Space Telescope. It also helped unite the Russian and American space programs when in 2005, the shuttle *Atlantis* docked with the Russian space station Mir.

The idea of reusable rockets dates back to the 1930s, when Viennese engineer Eugen Sänger (1905–1964) developed plans for a liquid-fueled craft capable of reaching the stratosphere. The idea of reusable rockets did not come to the forefront of imagination in the United States until the early 1950s. German scientist Wernher von Braun (1912–1977) was the most charismatic and effective promoter of this method of travel. In a series of articles for *Collier's* magazine (one of the most highly read periodicals in the United States at the time), he articulated many of the features eventually realized in the space shuttle. Reusable rockets remained in the background until the 1970s, when the space race to the moon between the Soviet Union and the United States came to an end.

After the final Apollo moon mission in 1972, NASA fundamentally reshaped its vision for space. NASA replaced voyages to the moon with a new low-earth-orbit destination accessed by a reusable space

shuttle that launched like a rocket and returned to Earth like a giant glider.

While NASA engineers were initially disappointed that another high-profile mission was not going to replace Apollo, they soon learned to appreciate the challenge of reusability. The idea of reusability was also related to a cultural emphasis on conservation and recycling. In an era of environmental consciousness, Apollo looked expensive and wasteful. For the space shuttle, the majority of the craft (except for the external tank that burned up in the atmosphere), could be used again and again.

Though the Space Shuttle program was a NASA project, Lockheed Martin constructed the external tank, Boeing and Rockwell developed the orbiter, and Thiokol manufactured the reusable solid rocket motor. All of the space shuttles launched from NASA's Kennedy Space Center in Florida. Landings also occurred there, as well as at Edwards Air Force Base in California.

The space shuttle itself was 184 feet in length, while the orbiter was 122 feet. At liftoff, it weighed 4.5 million pounds, and once in orbit, its velocity was 17,321 miles per hour, which meant that the crew witnessed a sunrise or sunset every 45 minutes. Each of its missions cost roughly half a billion dollars and lasted from 10 days to two weeks, during which time the astronauts performed zero-gravity science experiments or other mission-specific tasks. Shuttles had a large bay in which they could transport cargo, like satellites, science equipment, or material for experiments. The bay also held the robotic manipulator arm.

Prior to the first actual mission in 1981, there were three prototype flights with the *Enterprise*. Piggy-backed on a modified Boeing 747 airliner, this Shuttle Carrier Aircraft (SCA) released the *Enterprise* in flight and enabled the astronauts to practice the gliding landing. The SCA also was the vehicle that transported the space shuttle cross-country to Florida when it landed in California.

The first launch, known as STS-1, took place on April 12, 1981, which ironically was exactly the 20th anniversary of Yuri Gagarin (1934–1968), the Soviet cosmonaut, becoming the first human in space. John Young and Robert Crippen were the first astronauts to pilot the *Columbia* on its maiden mission.

The shuttle program came to represent the diversity of American society itself. While the early astronauts were all white males, this changed by the 1980s. In June 1983, Sally Ride became the first American woman in space, and two months later, Guion Bluford became the first African American in space. Hispanics also made their first ventures in this decade with Frank Chang-Diaz's trip in 1986. In 1992, Mae Jemison became the first African American woman in space, and one year later, Ellen Ochoa became the first Hispanic woman there. The other important way that the shuttle mirrored American society was with the inclusion of a senior citizen. NASA did this with a notable name from the past, as John Glenn became the oldest human to fly in space at age 77. The final multicultural achievement was the 2002 shuttle flight of J. B. Herrington, the first tribal-registered Native American to fly in space.

Tragically, the Space Shuttle program will also be remembered for two catastrophic failures. On January 28, 1986, the shuttle *Challenger* lifted off from Cape Canaveral and minutes later exploded over the Atlantic Ocean, killing its crew. This signified the greatest disaster in NASA history and the first time that any American astronaut was ever lost in flight. It became one of the most traumatic moments ever captured on live television. This mission included the first "teacher in space," Christa McAuliffe (1948–1986), and millions of schoolchildren across the nation were watching the launch live on television.

The *Challenger* disaster resulted in a 32-month break in the shuttle program and a months-long investigation. The Rogers Commission determined that the shuttle's O-rings had failed as the result of a design flaw. The commission also found significant communication failures between mission engineers, safety personnel, and high-ranking NASA managers.

Though the space shuttle returned to operational duty, tragedy again marred the program when the *Columbia* disintegrated while reentering the atmosphere over Texas on February 1, 2003, killing all seven members of its crew. The *Columbia*, which was the first shuttle in space, made 27 missions before its 2003 disaster. Many NASA critics argue that the *Columbia* accident was the result of NASA's refusal to institute meaningful institutional change after the *Challenger*

disaster, including the failure to set up a truly independent office for safety.

The final mission, by the space shuttle *Atlantis*, landed at Kennedy Space Center in July 2011. In total, the five shuttle orbiters had logged over a half billion miles in space. There were 335 astronauts that flew on the space shuttle, with 14 dying in the two failed missions.

The shuttle's impact was felt on earth as well as space with several technological spin-offs from the program. These included small artificial heart pumps developed from shuttle fuel pump technology. The shuttle team helped to develop environmentally friendly lubricants. Homeowners now insulate their residences using light, flexible aerogel that NASA developed to insulate shuttle cryogenics. Other shuttle spin-offs include firefighting infrared cameras, prosthesis materials, video stabilization software, land mine removal devices, automotive insulation, and handheld cutters to remove people trapped in wrecked vehicles.

Until another craft is developed, U.S. astronauts rely on the Russian Soyuz spacecraft to reach low-earth-orbit destinations like the International Space Station. The three surviving shuttles are now museum pieces. *Atlantis* is displayed at Kennedy Space Center, the Smithsonian houses the *Discovery*, and *Endeavour* resides at the California Science Center in Los Angeles.

Strategic Defense Initiative (SDI)

President Ronald Reagan proposed the Strategic Defense Initiative (SDI), a nuclear missile-proof bubble over the United States nicknamed “Star Wars” after the popular science fiction film created by George Lucas in 1977. SDI forerunners Sentinel and Safeguard were terminated, because they were incapable of fulfilling their enormous missions. SDI challenged the long-standing deterrence theory (a reliance on the threat of nuclear retaliation to discourage attack) by threatening to shift the balance of defense capabilities.

Although SDI never worked the way it was intended and was extremely expensive and controversial, it may have helped to bring about the end of the Cold War. Congress cut SDI’s budget dramatically in 1992; however, the threat of terrorism after 2000 enabled President George W. Bush to begin construction of the National Missile Defense (NMD) system, which came to be known as the “Son of Star Wars” program.

During World War II (1939–1945), German scientists attempted to develop intercontinental ballistic missiles (ICBMs), long-range missiles that could hit targets in other continents. In response, the United States commissioned American scientists to conduct missile defense research. In 1945, Edward Teller (1908–2003), later known as the “father of the hydrogen bomb,” wrote a report for the U.S. Navy about the feasibility of defensive capabilities against atomic weapons.

By the 1960s, ICBM technology had been developed, and it was in the hands of the two Cold War (1945–1989) superpowers: the United States and the Soviet Union. In 1966, Teller invited California governor Ronald Reagan to a weapons laboratory in

Livermore, California, for a two-hour briefing on his work with missile defense. Although Teller’s main goal at that time was to secure state support for his research, the meeting left a lasting impression on Reagan.

In 1967, the Soviet Union deployed a missile defense system that used missiles to shoot down other missiles. That same year, President Lyndon B. Johnson ordered the deployment of a U.S. counterpart called Sentinel, which was intended to defend large U.S. cities against incoming missiles. However, if only one nuclear missile got through Sentinel’s defenses, it would spell disaster for any large city. In 1969, President Richard Nixon replaced Sentinel with Safeguard, a plan to defend vital U.S. weapons systems. Like Sentinel, Safeguard was too small to fulfill its huge task. In 1972, Congress cut Safeguard’s funding, and the program was terminated in 1976.

Many American and Soviet leaders came to the conclusion that no technology existed that could provide adequate defense from incoming missiles. Furthermore, if such a system could be developed and deployed by one of the superpowers, it would leave the other nation at a great military disadvantage. Some even argued that an attempt by one of these two nations to develop an effective missile defense system could lead to nuclear war because of pressure placed on the other nation to launch an attack before its defense system was completed.

Since 1949, when the Soviets tested their first atomic bomb, diplomats had relied on the theory of deterrence. The fact that both the United States and the Soviets had atomic bomb technology deterred each nation from using them for fear of retaliation from the other. In 1972, American diplomatic negotiations with the Soviets culminated in the Strategic Arms Limitation Talks (SALT) and the Anti-Ballistic Missile Treaty (ABM), which limited each of the two nations to a maximum of two missile defense sites (each with a maximum of 100 interceptor missiles). In 1974, the two nations signed a follow-up protocol that reduced the missile defense sites to one for each nation.

In 1982, Teller gave a presentation to President Reagan on strategic defense. The next year, Reagan gave a speech (based on Teller’s report) before Congress on the need to fund SDI. The original vision for

SDI was a system of space-based laser-firing satellites. The original plan to put weapons in outer space would have violated the Outer Space Treaty (1967), which had been signed by both the United States and the Soviet Union. Later proposed designs for SDI included land-based weapons that would shoot down missiles with other missiles, subatomic particle beams, or electromagnetic rail guns. All of these proposals would have violated the 1972 ABM Treaty.

Scientists were unable to make the SDI dream a reality. Officials from the U.S. Defense Department estimated that it would take at least 30 years to construct and deploy an effective SDI system. Due to the fact that all of the different versions of SDI required a high level of technological, futuristic know-how that did not exist, journalists created the nickname “Star Wars” for it.

After a decade of research and development, a Congressional report put the total cost of SDI at \$70 billion. Critics charged that SDI was a waste of money. According to some historians, however, Reagan’s commitment to SDI and the Soviet Union’s inability to keep up with U.S. defense spending contributed to the collapse of the Soviet economy. According to this view, by outspending the Soviets, Reagan helped bring about the end of the Cold War in 1989.

After the Cold War, Congress cut SDI funding dramatically. In 2000, President George W. Bush announced that he would replace SDI with NMD, a less expensive missile defense system. NMD created a layered defense system of land-based missiles in Alaska and California that could, theoretically, shoot down incoming missiles at various stages of their flight paths. As a result, the United States withdrew from the ABM Treaty in 2002. Analysts estimated the cumulative 30-year cost of SDI and NMD at \$100 billion.

Sustainable Agriculture

Sustainable agriculture is a way of farming that emphasizes a rejection of chemical fertilizers, pesticides, and genetically modified seeds while encouraging a more holistic and natural approach to the land. There are many ways to define sustainable agriculture; its meaning has been changing since the late 1980s. Although it is uncertain who originally created the term, the first person to publish the expression “sustainable agriculture” was Wes Jackson in *New Roots for Agriculture* (1980). As Jackson discusses, the need for sustainable agriculture springs from the fact that globally, crop and livestock production faces many challenges that cause it to be unsustainable. The existing problems with contemporary crop and livestock production and the global challenges that mainstream agriculture faces must be understood before more sustainable agricultural practices can be implemented.

As a result of the industrialization of agriculture, which started in the late 1800s and had its most recent push with the Green Revolution in the 1960s, the small, independent farm economy is currently in collapse. The U.S. agricultural economy is increasingly and extremely dependent on the use of inputs such as fertilizer, groundwater irrigation, and so on, and financial support by the government. The use of fertilizers in this country has led to huge “dead zones” along the Gulf of Mexico where the Mississippi River drains into the ocean. These dead zones are an ecological disaster caused by excessive use of fertilizers, which are mostly unabsorbed by crops and leach into the rivers.

Along with the Green Revolution came a dependency on fossil fuels to run farm equipment that allows for mass production and cultivation of crops. As fossil fuels become scarcer, the economic cost of fossil fuels increases, creating an inefficiency in energy use and costs. The use of fossil fuels is not only economically

nonviable but also contributes to another problem threatening mainstream agriculture: the burning of fossil fuels emits greenhouse gases that are scientifically proven to accelerate climate change. With every passing day, climate change becomes a more pressing global issue. The effects of climate change on global agriculture has been catastrophic in many cases. Climate change has increased the number of droughts and other extreme weather events that have led to or have been a key factor in all of the five famines happening right now around the world. Every one of these issues pushes the need for agricultural practices to become more sustainable economically, environmentally, and socially.

With these challenges in mind, the 1990 congressional Farm Bill defined sustainable agriculture as an integrated system of plant and animal production practices having a site-specific application that would, over the long term, meet certain criteria. Sustainable agriculture must satisfy human food and fiber needs, enhance the environmental quality and natural resource base upon which the agricultural economy depends, make the most efficient use of nonrenewable resources and on-farm resources, sustain the economic viability of farm operations, and enhance the quality of life of farmers and society as a whole.

Sustainable agriculture is meant to support the ecology of the land and efficiently produce food by managing the consumption of resources and minimizing waste. Wendell Berry said that for agriculture to be sustainable, “it must preserve the land, and the fertility and the ecological health of the land,” and “the people who use [the land] must know it well, must be highly motivated to use it well, must know how to use it well, must have time to use it well, and must be able to afford to use it well” (Berry 1990). This perspective on what constitutes productive agriculture agrees with the contemporary definition of sustainable agriculture: that it must be ecologically restorative, supported by society, and economically viable.

The answer to how to make current agricultural practices more sustainable is not simple. What makes some practices more sustainable than others depends on ecological characteristics and the climate of an area, among many other influences. As described in the 1990 Farm Bill, sustainable agricultural practices

are site specific, meaning that for people to create the most sustainable system of agriculture, they must have a comprehensive understanding of the ecology and climate in that area. Some practices that have increased the efficiency of crop production in terms of bushels per acre include advances in farming equipment, manipulation of genes through hybridization or transgenic crops (GMOs), improved farming techniques such as crop rotation, no-till farming, and cover crops. However, the list of different ways that farmers increase the yield, sustainability, or economic viability of their systems seems never to end.

Today, sustainable agriculture is more widespread and culturally meaningful than it has ever been. Women make up a significant number of new, sustainable farmers, and in the process, they are redefining the term “farmer.” The term “organic” is now commonly used in grocery stores. It seems to be possible to find an organic option for almost any grocery product. Organic farming is an agricultural practice that does not contribute to the problem of the “dead zones” and other ecological issues stemming from the use of synthetic fertilizers, herbicides, and pesticides. Organic farming has proved to be productive as long as it is managed well.

Instead of using synthetic fertilizers or animal derived fertilizers, farmers can grow “green manure crops,” which are basically cover crops such as lentils that can fix nitrogen back into the soil. Once these crops are grown, instead of harvesting them, farmers cut the crops off and till them into the soil to replenish its organic matter. Cover crops are crops that are planted to decrease soil erosion, weeds, and pests while also increasing soil quality and soil fertility. Cover crops work best in areas with higher levels of annual rainfall, such as in the eastern part of the United States, because they should improve the soil of the land and keep it free of weeds without using all of the water needed by the cash crop. Cover crops are an alternative to leaving a field fallow. In places of lower precipitation, such as in the western part of the United States like Montana and eastern Washington, it is common practice to leave a field fallow during the summer months so that precipitation soaks into the soil to be used by winter wheat or spring wheat once it is planted.

Modern farmers, particularly those wishing to resist the incursions of corporate agriculture, are increasingly turning to sustainable farming, particularly in light of the fact that multitudes of studies prove that agribusiness-driven monocultures are bad for the environment, bad for human health, and bad at feeding the world.

Wind Energy

Wind energy is a renewable energy source obtained by rotating blades of windmills or turbines via wind power. Wind energy has been used in daily work such as pumping water and grinding grain for over 4,000 years. However, in the 20th century, wind energy has been successfully and economically converted to general electricity production and the resultant power converted to the grid system.

The world's first wind farm was built in New Hampshire, with a capacity of 600 kilowatts (KW), in 1980. Since then, the United States and a few other European countries such as Germany, Denmark, and Holland have contributed significantly in improving

the design and efficiency of the wind energy generation system. In 2008, the United States surpassed long-time leader Germany by producing 20 gigawatts (GW) of wind energy. However, in 2013, most wind energy was produced by China (91.4 GW), followed by the United States (61.1 GW) and Germany (34.2 GW).

The wind energy generation system is divided into two major categories based on the size of the turbine and type of customer. They are as follows: “utility-scale” wind systems with large turbines (larger than 100 KW capacity), primarily used by the electric utility companies and power system operators; and “distributed,” or “small wind,” systems with turbines (100 KW or less capacity) that are used to provide electricity to residential homes, farms, or small businesses. There are also “off-shore” wind farms in coastal areas, which have experienced significant growth particularly in Europe due to the presence of stronger winds, better technologies, and less impact on real estate values. The top three countries with the largest off-shore wind capacities are the United Kingdom, Denmark, and Germany.

Wind turbines are complex systems and in need of technical expertise from many fields such as mechanical, electrical, electronics, construction engineering, and meteorology. Most wind turbines consist of a steel tubular tower, which supports both a “hub” securing wind turbine blades, and the “nacelle,” which houses the turbine's shaft, gearbox, generator, and controls. Wind rotates the turbine blades, and the rotating blades make an internal shaft spin; the shaft is connected to a gearbox, which increases the speed of rotation significantly. A generator connected to the gearbox then produces electricity; thus, wind energy is converted to mechanical energy and, in the end, to electrical energy. Wind assessment equipment in the control system helps the turbine to rotate into the face of the wind and to optimize energy captured by adjusting the angle, or “pitch,” of its blade.

The World Wind Energy Association (WWEA) is the driving force behind the promotion and deployment of this form of energy worldwide as a clean alternative to fossil fuel and nuclear energy. There are currently three different concepts available for generating electricity from the wind turbine: (1) the Danish concept, (2) the pitch concept with a synchronous generator, and (3) the pitch concept with a doubly

fed, asynchronous generator. Technical expertise as well as the implementation strategies, either for grid-connected or stand-alone wind turbines, are provided by the WWEA to its members. The WWEA expects that the demand for wind energy will grow at a faster pace in the near future, and it predicts that wind capacity will reach more than 700 GW by 2020.

In the United States, the American Wind Energy Association (AWEA), a not-for-profit organization, provides information to the general public and businesses about wind energy and endorses policy on Capitol Hill and across the states to enhance the future growth of wind energy. Its Web site is a valuable resource for finding all activities and information regarding wind energy. The Community Wind Working Group (CWWG) was formed by the AWEA in 2009 to pursue the growth and interest of “community wind” projects. These projects are controlled and financed by local landowners or individuals in agricultural or rural communities. Small or midsize wind turbines are used for these projects. The AWEA is also exploring the huge potential for launching the off-shore wind system. According to its data, off-shore systems are capable of generating up to four times the current capacity of the U.S. electrical system. The U.S. Department of Energy stated in its report that off-shore wind will contribute significantly to meeting the goal of “20% Wind Energy by 2030.” AWEA closely works with the U.S. Environmental Protection Agency to reduce emissions of greenhouse gases and is committed to meeting the growing need for energy in the United States. Research suggests that wind energy has several benefits, including a significant reduction of carbon dioxide, sulfur dioxide, and nitrous oxide emissions and the conservation of billions of gallons of water.

The drawbacks of wind energy are the high initial investment cost, the high noise level produced by the turbine blades, and the visual impact of the wind farms on the public. Also, the ecological impact of wind turbines on wildlife, particularly on bats, has been a major concern for environmentalists. AWEA and the wind industry have taken initiatives to reduce the harmful effect of turbines on bats and other wildlife. AWEA, Bat Conservation International, the U.S. Fish and Wildlife Service, and the National Renewable Energy Laboratory have formed the Bats and Wind

The wind farm at Altamont Pass is one of the nation's first of its type, and it remains the largest concentration of wind turbines in the world. (Terrance Emerson/Dreamstime.com)

Energy Cooperative (BWEC) to research the influence of wind turbines on bats and to investigate new techniques in reducing their harmful effects, such as acoustic deterrents and potential operational changes to wind turbines.

Wozniak, Steve (1950–)

Beside Bill Gates of Microsoft, Steve Wozniak is known as one of the electronic entrepreneurs who invented the information age by inventing the Apple personal computer and cofounding Apple Inc. Due to media coverage and his position as the top sales representative of the company, cofounder Steve Jobs gained more notoriety, but it was the technical talents of Wozniak that ensured that the company had a product worth selling. In later life, he left the company to new management and focused his attention on philanthropy.

He was born on August 11, 1950, in San Jose, California, to Margaret Elaine, who worked in the home, and Jerry Wozniak, who worked in the electrical engineering field and thus offered his son an early love of technology. His father’s position at Lockheed Missiles and Space Company meant the family kept abreast of the newest ideas emerging in the field. The Wozniaks valued education and its role in promising their children successful careers. Encouraged by both parents, Wozniak built ham radios and game devices while still in elementary school. He won awards for science and tech projects throughout his education and in high school helped his electronics teacher program computers at the local electronics company, Sylvania.

College proved more of a challenge as the young man moved from the University of Colorado, Boulder, to DeAnza Community College, to the University of California, Berkeley, which he attended in 1971. That summer, Wozniak worked on mainframe computers for Hewlett-Packard and eventually met fellow employee Steve Jobs. While they worked at Hewlett-

Packard by day, the two new friends attended meetings of the Silicon Valley Homebrew Computer Club at night. The Club became a hub of up-and-coming computer professionals and allowed Wozniak a sounding board for new ideas.

In 1973, Jobs began working at Atari Inc. and brought an offer to Wozniak to help create more efficient circuit boards for the company’s arcade games, an after-hours project that could earn them extra cash. Wozniak succeeded and they earned the bonus, though in later years, Wozniak discovered that Jobs had lied about how much it was and kept the lion’s share for himself, an act that harmed their friendship and business partnership.

Wanting to impress their friends in the Homebrew Club, Wozniak began working on what would become the Apple I personal computer in 1976. The desire to create something fun that focused on being user-friendly became a motto that continued to fuel the company he founded through its work on cell phones and beyond. Back then, all the electronic work—designing the hardware, the circuit boards, and the operating system—was done by Wozniak. Jobs handled the marketing and was the driving force behind the idea of forming a company to sell this new, user-friendly home computer. He formed a relationship with the Byte Shop, a computer sales office run by Paul Terrell in Mountain View, California. When the first 50 boards sold quickly, Terrell wanted more, and Wozniak and Jobs knew they had a valuable product on their hands.

At this point, Wozniak knew he could risk resigning from his job at Hewlett-Packard to focus on research and development of new products, which began with the Apple II, the first personal computer that could display color graphics and included the BASIC programming language. Soon he developed a way to connect the Apple computer to a printer, and then he developed the floppy disk for memory storage, acts that made their computers more and more popular with average, nonhobbyist consumers. By the end of 1978, Apple sales had increased 10 times, making Apple one of the fastest-growing companies in the United States. Thanks to Jobs’s efforts, more than 300 dealers carried Apple computers, and by 1979, Apple had more than a thousand employees.

This continued success convinced the partners that it was time to take the company public, an act that made them both millionaires in 1980. Wozniak started designing a new computer called the Lisa, named for his daughter, but it failed to catch hold of the now-cluttered personal computer market. He quickly reconfigured a cheaper version called a Macintosh, which came with a mouse, file folders, and pull-down menus and could display photos. This one sold. A flying accident took Wozniak away from his work for a time, but by 1983, he returned to the product development department to be the head engineer and motivational influence for the Apple workforce. By early 1985, Wozniak again left Apple and sold most of his stock.

As a philanthropist, Wozniak continued to focus on technology and bringing it to those less financially capable of purchasing high-end products. In 1990, he helped found the Electronic Frontier Foundation and was the founding sponsor of the Tech Museum, the Silicon Valley Ballet, and the Children’s Discovery Museum of San Jose. He also donates money and personal time to his local school district to make sure that students can work with the latest technology.

In his career, Wozniak has been honored with several major awards, including the 1979 ACM Grace Murray Hopper Award and the 1985 National Medal

of Technology (shared with Steve Jobs) from President Ronald Reagan. In September 2000, Wozniak was inducted into the National Inventors Hall of Fame, and in 2001, he was awarded the seventh annual Heinz Award for Technology, the Economy and Employment. Outside the United States, Wozniak was awarded the Global Award of the President of the Republic of Armenia for Outstanding Contribution to Humanity through IT in 2011. His other awards are too numerous to mention.

3. The New Millennium (2000–Present)

OVERVIEW

Technology and technological advances this millennium have surpassed even the expectations and dreams of the most avid science fiction fan. From the advent and evolution of the smartphone to the printing and cloning of human organs, technology's mandate to address the challenges of human existence has been met and continues to expand. New technological waves throughout this period have encompassed the arenas of communication, medicine, education, food-stuffs, and energy, to name a few. The federal government and major corporations like Apple, Amazon, Microsoft, Google, Intel, and Dell have continued to pioneer technology that changes people's interactions with each other and the world at large. In this current era in American technology, the sky is the limit.

Technological advancements in the areas of transportation and energy, such as electric cars and biofuels, are signifiers of the basic mandate of technology as a "practical" application of knowledge, as these technologies seek to advocate and support long-term protection of nature and natural resources. Here in the United States, the first successful electric car made its debut around 1890 thanks to William Morrison. His six-passenger vehicle capable of a top speed of 14 miles per hour was little more than an electrified wagon, but it helped spark interest in electric vehicles. Renewed interest in the electric car came with the introduction of the Toyota Prius in Japan. Before the Prius could be introduced in the United States, Honda released the Insight hybrid in 1999, making it the first hybrid sold in the States since the early 1900s. The other event that helped reshape the electric vehicles market was the announcement in 2006 of the Silicon

Valley-based Tesla Motors luxury electric sports car that could go more than 200 miles on a single charge. In 2010, Tesla established a manufacturing facility in California. In the short time since then, Tesla has won wide acclaim for its cars and has become the largest auto industry employer in California. Tesla's announcement and subsequent success spurred many big automakers to accelerate work on their own electric vehicles.

In late 2010, the Chevy Volt and the Nissan LEAF were released in the U.S. market. The Energy Department helped build a nationwide charging infrastructure, installing more than 18,000 residential, commercial, and public chargers across the country. Automakers and other private businesses also installed their own chargers at key locations in the United States, bringing today's total of public electric vehicle chargers to more than 8,000 different locations with more than 20,000 charging outlets. At the same time, new battery technology helped to improve a plug-in electric vehicle's range. In addition to the battery technology in nearly all of the first-generation hybrids, research also helped develop the lithium-ion battery technology used in the Volt. More recently, research and development helped cut electric vehicle battery costs by 50 percent by 2017 while simultaneously improving the vehicle batteries' performance. This has helped to make electric vehicles more affordable for the average consumer. Inquiries into alternative fuel sources by the federal government and corporations in America have evolved and improved to support the sustaining of energy resources. Alternative energy sources like Ivanpah, the largest concentrating solar power (CSP) plant in the world, located in the Mojave Desert of California, with a field of heliostat

mirrors have the capacity to generate enough clean electricity to power over 94,000 average American homes. The use of alternative processes for energy and material building has been a significant event during this period.

Seeing the World in 3-D

Alternative, 3-D technology has been part of the American scene since roughly 1915. However, since the beginning of the current (21st) century, advances and innovations in 3-D printing, 3-D television, and 3-D filmmaking have charted new pathways for entertainment, engineering, and medical advancements. The construction of a physical object from a three-dimensional digital model by creating and laying many thin layers of material atop one another is the process of 3-D printing. This manufacturing process has provided benefits to humankind in a variety of industries, such as building materials, space technology, automotive construction, civil engineering, fashion, and the creation of foods. It even has the potential to be used for biological organ creation.

In 2000, a Clemson University bioengineer modified inkjet printers to dispense biological ink and made 3-D objects. In 2007, one of the first bioprinting companies, Organovo, was founded. It has been successful to date with printing out liver tissue samples that are used for drug testing and research. The 3-D printer may be one of two common types. It may be a fused deposition modeling (FDM) printer, which is similar to a 2-D inkjet printer but having an extra axis enabling each layer to be formed when a thin stream of melted material is deposited through a spout. The other prominent model is the selective laser sintering (SLS) printer, which uses a scanning laser beam to build up an object from powdered material. Starting with a computer-aided design (CAD) file, the software slices the design into hundreds or thousands of horizontal layers. Once the 3-D printer has read the file, it creates each layer exactly. The layers are meshed together, creating a three-dimensional object. Another name for 3-D printing is “additive manufacturing,” as each part of the object is created in successive layers in what is an additive process. Today, basic 3-D printers are small enough to sit on a desktop, cost only a

few hundred dollars, and are available for anyone to buy. Additionally, 3-D printing can be done through Internet printing companies. Customers upload their 3-D printing files through an Internet-based service, choose the proper production selections, and submit. The object is printed at another location and then delivered to the customer. Alongside 3-D usage in the area of printing, technological developments in 3-D television have also found their way into the home of the average consumer.

3-D television provides depth perception for the viewer through the use of techniques such as stereoscopic display, multiview display, and 2D-plus-depth. Most modern 3-D television sets use an active shutter 3-D system or a polarized 3-D system, and some are autostereoscopic, allowing the viewer to watch shows in 3-D without special glasses. In early 2010, due to the popularity of 3-D in theaters, several companies, including LG, Phillips, and Sony, developed technology to create 3-D televisions as well as IMAX and Sony delving into creating 3-D television networks, like the short-lived 3Net carried on DirecTV from 2011 through 2014. By 2014, most 3-D television networks had come and gone due to a lack of demand for the service in homes.

Contemporary 3-D technology in filmmaking was primarily a feature in IMAX theaters and has been around since 1986, when the film *Transitions* became the first 3-D movie to be paired with polarized lenses rather than the typical anaglyph glasses. Polarized lenses permit an image to be emitted toward the viewer and then refracted through the glasses. Because each lens is polarized differently, the image received by each eye is different. Consequently, when the brain receives these two similar but different images, it combines them into one—a 3-D image. A 2004 documentary on the *Titanic* illustrated advances in HD video cameras and digital film, which soon found their way into the commercial film market with the release of the digitally remastered (DMR) IMAX 3-D movie *The Polar Express*. The success of this 3-D venture helped propel the competition as newer, more improved technologies began to emerge. These included the 2006 releases of *Monster House* and *The Nightmare Before Christmas* on XPAND 3D, RealD, and Dolby 3D. RealD 3-D cinema technology is a polarized 3-D

system that uses circularly polarized light to produce stereoscopic image projection. The MasterImage 3D MI-CLARITY3D system for cinemas is a differentiated 3-D system that is based on the projector presenting a spinning polarized filter, which contains alternating segments of circularly polarized material. Mounted in front of the projector lens, this filter is synchronized to the projected images, giving each frame a polarization perpendicular to the previous one, which can be viewed with polarized 3-D glasses. By 2007, the anaglyph glasses were replaced for the most part with polarized lenses or LCD shutter glasses. No other film exemplified the advancements in 3-D filmmaking then the highest-grossing film to date, James Cameron's *Avatar*, which was filmed with custom-built cameras and 3-D software.

The Impact of Laser Technology on Life

Important achievements in the technology of this time included ongoing developments in laser technology. Since the FDA approved lasers for the removal of facial wrinkles in 1996, the use of lasers for cosmetic treatments has boomed. Throughout the first decade and a half of the 21st century, the use of laser technology has expanded exponentially. Lasers are also used for treating industrial surfaces. They can toughen and blend surface materials in targeted areas with great precision. Laser-cutting of manufacturing parts reduces production costs. Color laser printers that could access the Internet were on the market by 2000, and by mid-2005, models from Samsung and Konica were affordable to the layman. Laser pointers have been used to distract basketball players on the free-throw line, made law enforcement officers worry that they're a target for snipers when they see laser light on their chests, and disrupted air travel. A major milestone in the laser industry came in 2006 with the introduction of the high-capacity optical-storage technology Blu-ray disc.

Laser application expanded throughout the first decade of the 2000s. One major factor in the United States was the growth in importance and enforcement of homeland security following the terrorist attacks of September 11, 2001. In 2003, the U.S. military began developing a system of green and red lasers for use in

the airspace around Washington, D.C. In operation by 2005, these beacons are visible up to 25 miles away and are used to warn pilots who enter the 2,000-square-mile air defense identification zone surrounding the nation's capital. In January 2010, high-power quantum cascade lasers (QCLs), with their widespread potential for applications in all areas of security, became part of the technological landscape. With an additional 150 different kinds of lasers for a variety of commercial and scientific uses such as tattoo and hair removal, the treatment of skin abnormalities, and general surgery, by the end of 2009, this technology was well established in many industrial laser processes. As of 2009, light-emitting diodes (LEDs) were penetrating the lighting market, while in Chicago, physicians at Rush-Presbyterian-St. Luke's Medical Center pioneered a new, if somewhat controversial, laser-based treatment for angina, the pain that accompanies heart disease.

Technology in the Medical World

Additional developments in medical technology occurred in AIDS and stem cell research, cloning techniques, and robotic surgery, among other areas. In 2002, the first rapid HIV diagnostic test for use in the United States that provides results with 99.6 percent accuracy in as little as 20 minutes was approved by the Food and Drug Administration, and in 2012, it also approved the first at-home HIV test. Although controversial since its inception, stem cell research advanced to the point that in February 2012, researchers at Cedars-Sinai Medical Center and Johns Hopkins University published results from a clinical trial in which adult stem cells were extracted from patients following a heart attack, new cells were grown in a petri dish, and these were then returned to the patient's heart. In the first demonstrated case of therapeutic regeneration, the treatment decreases scarring and leads to regrowth of heart tissue. In the cloning arena, John Sperling and his wife, Joan Hawthorne, opened Genetic Savings & Clone for the purpose of cloning pets for individuals who could afford to pay for the service. In 2001, the process was used to successfully clone a cat named Copy Cat, or CC, who had a litter of her own healthy kittens in 2006—the first time that a

cloned pet gave birth. In 2015 at Harvard University, processes were being invented and tested to save endangered species as well as leading to the possible cloning of extinct animals like the woolly mammoth.

Prosthetic and implant technology also significantly evolved during this time. Approximately 2 million amputees in the United States wear prosthetic limbs. Since the first-known wooden toe, prosthetic design has advanced to include high-performance running blades, sensors, and microprocessor-controlled responsive legs and feet for navigating varying terrain as well as motorized hand prosthetics. Developments in technologies such as robotics, brain-computer interfaces, and 3-D printing have helped advance the field of prosthetics. Robotic surgery, which uses a computer as a conduit between the surgeon and the surgical tools used on the patient, has been found to make surgery safer and more efficient. Robotics also offers motion scaling, which means that a surgeon's wide hand movements can be reduced to fine movements at about a one-tenth scale, allowing for accuracy in tight spaces. In 2000, the da Vinci Surgical System broke new ground by becoming the first robotic surgery system approved by the FDA for general laparoscopic surgery. Robotics-assisted surgery has become enormously popular around the world, with over 1.5 million procedures from hysterectomies to heart valve repairs performed in 2011 alone. By 2013, an FDA survey noted that surgeons who used da Vinci were able to have some patients with cancer avoid chemotherapy.

Technology in Education

From the operating room to the classroom, technological innovations are advancing the human condition. Since the founding of the Academy by Plato in 389 BC, education has been the heart of a civilized society, and technology has always been at the forefront of human education. In looking at where educational methods and tools have come from and where they are going in the future, technology's importance in the classroom is more evident now than ever. Educational technology is anything that enhances classroom learning in the utilization of blended or online learning. In the field of educational technology, one of the major sources of information utilized in this millennium is the Wikipedia online encyclopedia founded in 2001 by Larry

Sanger and Jimmy Wales. Wikipedia is an open-source, free online encyclopedia that aims to allow anyone to edit articles and is ranked among the 10 most popular Web sites globally. Originally only in English, Wikipedia has expanded and has articles in over 250 different languages, although the English-language version with over 5 million individual articles is still its most visited site. There are also learning management systems (LMSs) such as Blackboard, Canvas, and Moodle that are utilized in K-12 education, corporate training, and at colleges and universities. Learning management systems are software that can be used to deliver, track, and manage training and education. LMSs range from systems for managing training and educational records to software for distributing courses over the Internet and offering features for online collaboration. Moodle is a free-to-download open-source course management system that also has platforms for distance learning courses, as does Eliademy, another free, but cloud-based, course management system. Students growing up in this digital age have extensive exposure to a variety of media. Major high-tech companies such as Google, Verizon, and Microsoft have funded schools to allow them to teach students through technology. Canvas is another LMS that provides a modern user interface. Canvas operates as a software service using Amazon Web Services in the cloud. Additionally, classroom tools such as the iClicker, introduced in 2005, allow teachers to poll students and get results in real time. According to research by 2009, 97 percent of classrooms had one or more computers, and 93 percent of classroom computers had Internet access. For every five students, there was one computer. Instructors stated that 40 percent of students used computers often in their educational methods, in addition to interactive whiteboards and digital cameras. Of college students more recently, 89 percent owned a laptop, and over 85 percent had a smartphone (Pearson.com 2015).

Additional tools in technology and learning have coalesced with the emergence of the e-book and the e-reader. With the creation in the 1970s of the first e-book library known as Project Gutenberg, there was a need for a way to access these materials. An electronic book (or e-book) is a book publication made available in digital form, consisting of text, images, or both, readable on computer monitors or other

electronic devices. Not all e-books have a hard-copy equivalent. Almost any computer device that features a controllable viewing screen can also be used to read e-books, including desktop computers, laptops, tablets, and smartphones. However, it was not until Amazon unveiled the Kindle electronic book reader in 2007 that the e-book became a mainstay in the average American life. Produced under the direction of its founder and CEO, Jeff Bezos, Amazon's Kindle hit the market with 250 MB of internal storage and a six-inch display/touch screen. The original Kindle was only sold in the United States, and all available stock sold out within six hours. This limited showcase illustrated the demand for a product that allowed any reader to hold hundreds of books in their hands at once. New technology, added roughly every year since 2009, included larger display sizes, adjustable fonts, larger storage, a text-to-speech feature that allowed the Kindle to read books aloud to the reader, and the Paperwhite edition of the Kindle, whose LED lights allowed people to read in the dark. Due to the demand for this technology, Kindle software has been developed for use on numerous devices and platforms, including Microsoft Windows, iOS, BlackBerry, Mac OS X, Android, webOS, and Windows Phone. In April 2011, Kindle customers became able to borrow books from almost 12,000 of the nation's libraries that purchased digital or e-books. In an attempt to garner a part of the e-reader market, Barnes and Noble, in November 2009, released the Nook e-reader, which included a color touch screen and Wi-Fi accessibility. While still in production, the Nook and other e-reader technologies have never met the demand or customer appreciation of the Kindle. Subsequently, in April 2016, Amazon unveiled the Kindle Oasis. With one of the lightest weights in e-book history at 131 grams, a redesigned grip, buttons for page turning, and a charging cover that can give the reader up to months of battery life, the Kindle Oasis keeps Amazon at the fore of e-reader technology. A major component of the e-reader market is its touch screens. There are several uniquely different types of touch screen technologies with different methods of sensing touch.

Touch screen technology took a huge step into the limelight with the 2007 release of the Apple iPhone. The iPhone introduced an accurate, inexpensive,

multitouch screen. The multitouch screens used by the iPhone rely on a carefully etched matrix of capacitance-sensing wires. The iPhone revolutionized the cell phone industry, and the technology it displayed has changed the way people communicate. This new device introduced the world of mobile apps allowing and encouraging people to communicate with each other through programs like Skype, text messaging, and e-mail through mobile devices. Additionally, people view videos through YouTube and share photos instantaneously through Web sites like Instagram, Twitter, and Tumblr. Throughout its many incarnations, the iPhone has only risen in popularity, with an estimated 90 million Americans owning iPhones as of 2016. The iPhone also made it easy to play music without an additional MP3 player.

Advances in the production, distribution, and consumption of music have evolved to the point that one can consume an entire concert from the privacy of one's home. Apple in the 21st century began its current reign in advanced technology with the unveiling of the iPod MP3 music player, one of the most notable and revolutionary technologies to advance music enjoyment. Released by Apple Inc. in October 2001, the iPod was a portable electronic device for playing and storing digital audio and video files. Measuring four inches in height and weighing 6.5 ounces, at the time of its release with 5 GB of storage, it was touted as putting "1,000 songs in your pocket." The early iPod had a scroll wheel with four buttons and was only compatible with Mac products; users had to add music to their iPods from CDs or other online sources. Subsequent incarnations of the iPod could store photos; there was the iPod mini and also the Nano, which went on to become the largest-selling music player in history to date; there followed the iPod shuffle, the first MP3 player with flash memory—an electronic medium that can be electrically erased and reprogrammed. The iPod touch was hailed as an iPhone without a phone or camera. Released in September 2007, it used the same operating system as the iPhone and offered double the storage capacity.

Technology Turns the Music World Upside Down

Meanwhile, at the production level, recording and mixing of sound have seen massive advances. There

are a tremendous number of devices available to the modern musician, from DAWs to synthesizers, to social media and music-streaming services. The availability of these technologies finally took music out of the hands of record labels and placed it in the hands of music makers. Music-editing software, or digital audio workstations (DAWs) exist today that are priced under \$100, are easy to learn, and accessible to the novice mixer. There are many free and open-source software programs that can enable a DAW. Digital audio programs such as *JACK* allows any JACK-aware audio software to connect to any other audio software running on a computer system. This allows mixers to use multiple programs for editing and synthesizing, as well as ensuring sound quality. Another program, *Audacity*, is a free, open-source digital audio editor that can run on Microsoft Windows but also on OSX and Linux. It is particularly popular in the podcast community. Other open-source music production programs include virtual synthesizers and MIDI controllers. Technology in the form of software and file sharing has also heavily affected and influenced the consumption of entertainment like music and films.

The leader in portable music and media distribution, Apple iTunes, was introduced in January 2001 and originally was only available for use on the Mac operating system. The original iTunes digital jukebox software started off as a way to access and play music. In 2003, the iTunes Music Store, with 200,000 songs at 99 cents each, was introduced. An expanded user base followed as iTunes version 4.1 added support for Microsoft Windows platforms. By 2006, iTunes sold its billionth song while also selling feature-length movies and television show episodes. Since its inception, it has developed into a sophisticated multimedia content mainstay. Currently, the iTunes store allows its users to purchase music, films, television shows, audiobooks, and applications; they can also manage media, create playlists, and synchronize content across multiple devices and operating systems.

Broadening the Technological Playing Field through Open-Source Software

Other forms of entertainment distribution have also found their way onto the scene through open-source

file-sharing technology. File sharing is the free distribution and providing of access to digital media such as computer programs, audio and video files, and even e-books. Major software platforms that employed this technology were LimeWire and BitTorrent. Open-source technology is software that is freely distributed and allows distribution in source code as well as compiled form. There must be an easily found means of obtaining the source code for no more than a reasonable reproduction cost, preferably downloading via the Internet without charge. The purpose is to make evolution of the software easy; therefore, access to modification must be easy. In 2000, the StarOffice office suite was released as free software, and in the summer of 2003, the Wikimedia Foundation was announced and became integral to the development of Wikipedia, an online collaborative encyclopedia written for and by the people who use it. Mozilla Firefox, a popular Web browser, was released in 2004. In 2008, Chromium, which forms the majority of the code in Google Chrome, was released. During this time, Google created and released Android, initially giving it away for free. Android has since become the most popular mobile platform in the world. Chromium OS, released by Google in 2009, has since been employed in a variety of devices, including Chromebooks. Currently, the number of open-source software packages in use is so large that it is virtually impossible to make a comprehensive list. Adding to the success and continued expansion of file sharing are the search engines, which have also evolved and become mainstays of the technological revolution.

Search Engines Became the Card Catalogs of the Future

Search engines use “spiders,” which search the Web for information. They are software programs that request pages much like regular browsers do. In addition to reading the contents of pages for indexing, spiders also record links. There are also search engines that use a search model in which they do not gather, warehouse, or sell data that identifies the user. All major search engines have a limited review process; relevant information is driven by automated search algorithms. Innovative technology in search engines has included providing almost immediate search results, product ratings, conversions

of units and currency, the ability to perform simple mathematical calculations, definitions of terminology, and even document language translation. Pay-per-click ads allow search engines to sell targeted traffic to advertisers on a cost-per-click basis. Typically, pay-per-click ads are keyword directed, but some engines may use local targeting, behavioral targeting, or allow merchants to bid on traffic currents based on demographics. Private search is also finding a market, but it still represents a tiny fraction of overall search engine usage.

Google has become and remained the leader in search engine technology. Since 2003, Google has come out with many advanced filters and crawling patterns to help make links easier to access. Google has also exponentially expanded its search engine domain with the 2004 launches of Gmail and Google Scholar, an academic search program, and the early 2005 introduction of Google Maps. The contemporary search engine market is controlled by a few large companies whose combined search volume makes up over 97 percent of the total global market. Google is in the lead, followed by Bing and Yahoo. In 2011, Google, Yahoo, and Microsoft created Schema.org to support a fuller range of tags that Web sites use to convey better information, illustrating the constant updating and upgrading of the search process. Google is used more in mobile searches because of a deal with Android phone manufacturers to set Google as the default search provider as well as signing a deal with Apple to be the default Web search service in Safari on iPhones, iPads, and Mac computers. Advances such as these in software and Internet use are supported by improvements in the hardware that is used to access it.

Taking Your Tech with You Everywhere

Portable devices with the ability to provide wireless connectivity to games, news, and entertainment, like laptops, iPads, and tablets, have transformed the human condition through changing the way information is processed and communication is proffered. Although the personal computer has been in production in one form or another since the 1980s, a pivotal moment in personal computing history came in 2002 when Microsoft updated the operating system of its tabletop personal computer to Windows XP. Personal mobile

computers took off, aided by the introduction and widespread availability of Wi-Fi in the home and designated “hotspots” throughout the landscape. Companies like Dell, Hewlett-Packard, and Sony all worked to get into the laptop market, juggling to provide the lightest and most user-friendly models. However, most notable was the April 2010 introduction of the Apple iPad, which revolutionized personal computing. The iPad can shoot video, take photos, play music, browse the Web, and receive and send e-mail. From its original inception, the iPad has evolved to include a mini iPad and retina display. Since the takeover of the tablet market by Apple, other companies, most notably Samsung with an Android operating system, have provided alternative platforms for tablet use. New technology on the market includes the phablet, a phone-and-tablet hybrid.

The mobility of personal computing and access to the Internet has led to the largest engagement with digital mediums in humankind’s history. The 21st century has seen the exponential growth of social media and social networking sites. Social networks seem to fulfill our need to connect with one another. The social life that people once found in face-to-face communities is now found in online communities. There are many prominent social networking sites used by both the individual and the corporate world. Sites like LinkedIn (2002), a business connection site; Myspace (2003); and Twitter (2006) have illustrated the power of technology to shape and mediate the human experience. One of the giants in this spectrum is the video-sharing site YouTube. With the motto “Broadcast Yourself,” this site is arguably one of the foremost sources of social networking and social media. The leader in this area as of 2018 is Facebook, yet it also serves as an example of how swiftly customer tastes change, as it completely displaced Myspace when it arrived in 2004. Founded in a dorm room by Mark Zuckerberg, Facebook has grown from a college networking site to the largest networking connector on the planet. Facebook is available in over 70 different languages and is found on every continent on the planet. Facebook technology is entrenched in all aspects of American and global culture.

Technology and continued technological advancement in the United States is not just for the scientific community. It has become so embedded as part of the

infrastructure of American society that a fair was created to celebrate it. Founded in the San Francisco area in 2006, Maker Faire is a gathering of inventors, educators, writers, artists, and tech enthusiasts who come together to share and celebrate technology. It is a forum to showcase innovation across multiple creative platforms, including engineering and art. By 2014, this event had spread globally, and at least 130 independently sponsored Maker Faires and mini Maker Faires have been held in places like Tokyo, Sweden, and Rome. This technological expo also expanded across the United States, with Faires in Detroit and New York, among other places. Makers and consumers of technology gather globally to show what they have created and share what they have learned, often making visible ideas and concepts that are out of the ordinary and may change human lives for the better—illustrating, as this phenomenon continues to spread, the enduring desire to meet and conquer the challenges of human existence.

Airplane Deicer

The airplane deicer, invented by Leonard A. Haslim in 1988, significantly improved air travel safety by keeping ice off airplane wings, not only in cold weather, but as airplanes fly at cruising altitude, where the air is cold, thin, and low pressure.

As airplanes climb to cruising altitude at about 35,000 feet, the increased speed of the aircraft combined with the low air temperature results in the formation of ice on the wings. This makes the control surfaces such as flaps and ailerons to become immobile, making it impossible to control the aircraft. Additionally, ice on the wing decreases aircraft performance as it adds weight, creating drag and reducing lift, causing aircraft emergencies and crashes.

Leonard A. Haslim, senior engineer at NASA Ames Research Center, invented a system known as the Electro-Expulsive Separation System (EESS). The EESS consists of an elastic, rubberlike deicer boot on the wing’s leading edge with layers of flexible, conducting copper ribbons that are integrated within the boot. When ice builds up on the wing’s leading edge, an electric current is sent through the conductors, causing them to pulse. The pulse is discharged in less than a millisecond, instantly inducing the conductor pairs to repel each other and explosively expand the slit voids between the conductor layers. The ice is immediately shattered into harmless particles that are removed from the wing. This invention earned him the NASA Inventor of the Year Award in 1988.

The EESS trumped the limitations of other existing deicers. In the case of using bleed air to melt the wing ice, the air bled reduces the engine thrust and also increases fuel consumption. Pneumatic boots work slowly and are useful mostly when there is significant ice buildup on the wing. Additionally, they break the ice into big chunks that are harmful to engines and the airfoils. Thermal deicers, although fairly common, require a huge amount of energy—tens of thousands of watts compared to 600 to 900 watts for the EESS. This means that the EESS has lower operating costs. Combined with its lighter weight, this makes it the most efficient method of deicing aircraft. This system was patented by Ames, who then licensed it to Ice Management Systems Inc.

(IMS) of Temecula, California, which made it commercially available.

In 1995, Richard Olson, the CEO of IMS, introduced the electroexpulsive deicing systems to the private sector, starting with Thompson Ramo Woolridge (TRW), who bought the technology for use on a new line of planes. The latest use for this NASA spin-off technology is on unmanned aerial vehicles (UAVs). UAVs are well known for their lightweight and long-duration flights; thus, the previous solutions for deicing were impractical for them. Electroexpulsive technology with its low power requirement and effectiveness on ice of any thickness makes it the best option for UAVs.

There also many other potential uses for these systems, not only in aerospace systems but also in the automotive sector. For vehicles, the EESS can be modified for windshields, eliminating the need to use ice scrapers. Another potential use is in ship deicing. Moreover, EESS technology can be used for bridge deicing. Electroexpulsive technology might have endless uses; however, extensive research on it is still required.

Amazon Web Services

Amazon Web Services (AWS) is a comprehensive cloud computing platform provided by Amazon.com, which began offering services for Web sites and client-side applications in 2006. Since its establishment, AWS has expanded by taking steps to secure its services, but it has experienced several major service interruptions over the years. AWS is both popular and profitable, and it may alter world business infrastructure.

Some of the most popular AWS services include CloudDrive, which allows users to upload and download

music, videos, documents, and photos with the use of Web-connected computers and devices; CloudSearch, a scalable search service; Dynamo Database, a scalable database service; Elastic Computer Cloud, which functions as a set of virtual machines that can run application programs; ElastiCache, which speeds up dynamic Web applications by alleviating database load; Mechanical Turk, which uses the intelligence of a network of humans to perform tasks that computers are ill-suited to do, including writing product descriptions; RedShift, a petabyte-scale data warehouse service connected to business intelligence tools; and Simple Storage Service, a high-speed, online backup for data and application programs. Amazon.com charges for services based on usage, and the rates vary for each service.

To minimize the effects of outages and to ensure the security of stored data, AWS is spread over several global regions. Central hubs are located in the Eastern United States, Western United States, Brazil, Ireland, Singapore, Japan, and Australia. Each of the central hubs is made up of smaller areas called “availability zones.” In spite of these precautions, AWS experienced several major outages in 2011, 2012, and 2017. Amazon.com boasts about its low AWS start-up and operating costs, and it has attracted a lot of Web site- and technology-related business subscribers. For example, Simple Storage Service alone earned \$1.17 billion in 2014. The next year, it reported a 78 percent increase at \$2.1 billion. In 2015, Amazon.com founder Jeff Bezos described AWS as a \$5 billion-a-year business. Worldwide, AWS has over 1 million customers. Every year, it is expanding into more facets of everyday technology-related services. For example, Netflix relies on AWS to manage and provide its online content, and Spotify uses AWS to quickly provide expanded storage needs to its customers. The number of businesses that rely on AWS is extensive and continually rising. Some of these businesses include Yelp, Comcast, Johnson & Johnson, Pfizer, and Kellogg’s. In 2016, AWS received a \$600 million contract from the Central Intelligence Agency. Critics concerned with national security leaks have issued cautions about the unstable nature of online security.

AWS promises to make it possible for business owners to build a technology infrastructure with a tiny operation team. Besides streamlining the start-up

process, it offers tools that business owners can use to analyze business trends and help them make better-informed business decisions more quickly. In short, AWS may alter the traditional structure of business technology support departments and ultimately the way businesses are run.

Amazon.com

As of 2017, Amazon.com was one of the world’s largest online retailers. Jeff Bezos started the company in a region with a technologically skilled workforce. By selling a handful of products, Bezos grew his company to the point that it boasted a variety of products spanning from A to Z. Expansion and reinvestment stifled profits during the early years, but the company began to skyrocket by the early 2000s. Bezos’s faith in the commercial value of technological innovation has greatly contributed to Amazon’s success.

In the early 1990s, Bezos was vice president of D. E. Shaw, a Wall Street firm. During these years, the popularity of the Internet grew steadily as businesses and homes increasingly connected their computers to the World Wide Web. Businessmen began looking for ways to use the new technology to increase sales. After Bezos read a report that projected a growth of annual Web use of 2,300 percent, he quit his job and set out to build his own online store. In 1994, Bezos drew up a list of 20 products that he believed were ideal for Internet commerce. After narrowing the list down to five items (compact discs, computer software, computer hardware, videos, and books), he started Cadabra (the temporary first name of his new company) in Seattle, Washington. He chose Cadabra’s location based on how it promoted the sale of the items on his list and how he hoped it would fill the company’s technological needs. Seattle was close to a large book distribution center, and it had a large technology-literate workforce.

At Bezos’s instruction, employees built a customer-friendly Web site that offered strong search capabilities for customers who knew exactly what they were looking for and general categories of interest for customers who were just looking for something to purchase. In addition, the site kept track of past purchases and used that information to make product recommendations based on each customer’s interests. The site allowed customers to post product reviews and allowed them to view reviews posted by others. Customers had the opportunity to sign up for e-mail alerts, letting them know when certain products were available for purchase. As a bonus, the site offered a book gift-wrapping option for a small fee. By the summer of 1995, the company (renamed Amazon) was fully online.

During the first few years, books accounted for most of the company’s sales. Amazon kept book prices low by filling orders directly from wholesalers and publishers. Surprisingly, by using this method, Amazon was able to offer over 1 million different titles with only an on-hand inventory of about 2,000 books in Bezos’s garage. Yahoo (a popular Web portal) listed Amazon on its “What’s Cool” list, and Netscape (a popular Web browser) listed it on its “What’s New” list. The promotion led to greater book sales. By 1996, Bezos’s garage was too small to keep up with the worldwide demand, so he drew up expansion plans. Amazon’s greatest advantage was that it could offer a much wider variety of products than most brick-and-mortar stores. Amazon’s major drawback, however, was that brick-and-mortar stores could deliver products to customers much faster than online stores could. Consequently, shortening delivery times was a major priority for Amazon, but more capital was needed to put the next step of Bezos’s plan into action.

In 1997 (only two years after Bezos launched the Web site), Amazon became a public company. Bezos used the shareholders’ investments to further expand product offerings and to greatly improve shipping speeds. To accomplish these two major goals, he expanded the Seattle warehouse by 70 percent and opened an East Coast distribution facility in New Castle, Delaware. By increasing the number of on-hand products and by operating two large facilities in different parts of the country, Bezos hoped to offer same-day shipping on 95 percent of all in-stock orders. While competitive prices and the convenience of online

A consumer shops online using Amazon.com. No longer constrained by brick-and-mortar stores that must close at certain hours, online shopping allows consumers to buy whenever the mood strikes. (Tatty/Dreamstime.com)

shopping continued to draw more customers, Amazon's emphasis on good customer service retained many of them. A few months after going public, Amazon became the first Internet retailer to secure 1 million customers. In 1997, Amazon reported \$147.8 million in sales. Just six months later (in 1998), Amazon attracted a million more new customers. By 1998, Amazon became the third-largest bookseller in the United States.

Although Amazon's book sales were huge and growing, Bezos was not content with selling only books. He wanted greater market share, which required investment in continued expansion. To make it easier for customers to navigate through a wider inventory as Amazon added new products, the Web site was organized into product categories (called "stores"). In addition, Bezos believed that technology held great promise in commerce, so he constantly reinvested large portions of Amazon's revenue in technological innovation. These two guiding principles made some investors unhappy, because they preferred immediate profits

rather than long-term reinvestments. In spite of some objections, in 1998 Bezos pressed on with his expansion plan by purchasing Bookpages (the largest online bookseller in the United Kingdom) and Telebook (the largest online bookseller in Germany). The acquisitions gave Amazon much greater access to the European book market. In turn, European books became more accessible in the United States. Bezos also purchased Internet Movie Database (IMDB). IMDB's existing company resources enabled Amazon to easily enter the video download market. That same year, Amazon entered into direct competition with Apple by expanding into the music digital download market. Amazon's new music store of about a quarter of a million songs allowed customers to search for music by artist, song title, or label. Customers were also able to listen to song sound clips to help them decide what to purchase.

In 1999, Amazon expanded into the toy, electronics, tool, and lawn furniture markets. That same year, Amazon's annual sales reached a new high of \$1.6

billion, and *Time* named Bezos the magazine's "Person of the Year." Bezos's determination to keep reinvesting in the company had resulted in seven years of great and continually growing sales, but no profits. Perhaps due to mounting pressure from shareholders, Bezos slightly modified his plan in 2001. He cut costs by laying off 1,300 employees and by closing a distribution facility. That year, Amazon had \$3.12 billion in sales with a \$5 million profit. In 2002, Amazon expanded into the clothing market with retail ties to The Gap and Land's End, and it earned a \$3 million profit—the second annual net profit in the history of the company. Although profits were low compared to sales figures, the fact that Amazon had finally become profitable garnered greater share values and greater public confidence in the future of the company. In 2004, Amazon reached a new high in sales at \$7 billion, and it netted an unprecedented profit of \$588.5 million. In 2008, company sales reached \$19.2 billion with a profit of \$645 million. Even during the recession of 2009, sales reached \$24.5 billion with a profit of \$902 million. Economists credited Amazon sales and profits to the wide variety of products and to its large, loyal customer base.

One of the most popular technological innovations included the Kindle. Although Kindle was not the first e-book reader on the market, innovative features such as its crystal-clear display attracted many consumers. The Kindle generated steady profits, because a demand for Kindles was directly tied to a demand for Amazon digital books. In fact, on Christmas Day 2009, Amazon sold more digital books than printed books. The Kindle Fire (a comparatively low-priced tablet with color display) was Amazon's bestselling product during 2010 Black Friday sales. As the Kindle encouraged digital book sales, the Kindle Fire encouraged Amazon app, music, audiobook, and video sales. Other innovations included Amazon Web Services (AWS), which allowed subscribers to use the computing power of Amazon's servers for Web-related services (including Web design). In an attempt to keep Amazon's large customer base, Bezos introduced Amazon Prime, an annual subscription that gave members free shipping on Amazon products. By 2013, Prime had 16.7 million members.

Before 2010, online shopping was exempt from sales tax in all 50 states. However, since that time,

some states have begun charging sales tax on Amazon purchases. The change resulted in a dip in sales. Consequently, Amazon sought to overturn the tax laws, but it was unsuccessful. In 2013, Bezos announced his plan to use drones to deliver packages to customers' front doors in urban areas within 30 minutes after they had been ordered. However, due to federal rules regulating air travel, as of 2017, the plan was still in the prototype stage. Another concurrent project targeted outer space. Bezos sold an undisclosed amount of his Amazon stock to create and fund Blue Origin, a private aerospace company devoted to manufacturing reusable rocket technology.

Artificial Memories

Artificial memory is a concept that involves implanting ideas inside an individual's mind, with the expectation of a change in behavior when they awaken.

French scientists are experimenting with animals in hopes of altering their behavior after ingrainings false memories. At France's National Center for Scientific Research, Karim Benchenane and his team are implanting electrodes similar to GPS devices in regions of the brains of mice. Scientists are targeting the medial forebrain bundle and the CA1 region of the hippocampus, which is composed of at least three different cell types that encode the memories needed for spatial navigation. By observing the behavior of the mice and noticing reactions as neurons fire as the animal moves around certain areas, scientists are analyzing their procedures.

These studies allow scientists to understand if cells encode the same kind of information during sleep as they do when the subject is awake. New discoveries also provide further information on the important role that sleeping plays in creating false memories. Psychologist Beth Loftus has proven that memories can be embedded into the mind without the use of advanced technology, as in one recent study, almost three-quarters of the participants reported having clear false memories of a crime they had not committed. By understanding the brain activity associated with the formation of false memories, discoveries in this field can help researchers find ways of preventing memory formations related to stress and sleep deprivation.

Bashen, Janet (1957–)

Janet Bashen is an African American inventor, entrepreneur, and businesswoman. Bashen is the founder and CEO of the Bashen Corporation, a national labor and employment consulting firm that investigates Equal Employment Opportunity (EEO) complaints under Title VII of the 1964 Civil Rights Act. When Bashen determined that an Internet software application was required to add efficiencies to the antiquated paper process used by most organizations at the time, she invented an ingenious Web-based software tool called LinkLine. She invented this software system as a way to file EEO complaints. She is the first African American woman to hold a patent for a piece of software.

Bashen was born on February 12, 1957. She founded her company in 1994, building its foundations in her home at the kitchen table. In 2001, Bashen's company was significantly expanding and she then invented the Web-based software for the EEO filing system,

LinkLine. LinkLine is a Web-based application for EEO claims intake and tracking, claims management, document management, and numerous reports. In 2006, Bashen joined an elite group of African American inventors when her patent was approved.

As an African American businesswoman, Bashen had to be very aggressive to establish solid and immediate credibility with her prospective clients. She had to persuade them that her business was capable of improving the way that EEO fair employment and opportunities investigation services were addressed. Currently, Bashen Corporation has investigated over 34,000 EEO charges and other complaints on behalf of their diverse nationwide clients.

Today, Bashen Corporation has become the preferred firm in the United States for human resources consulting with its EEO compliance consulting services. Bashen has developed successful programs for various organizations, including numerous Fortune 500 companies, health care providers, educational institutions, federal agencies, insurance carriers, financial institutions, and nonprofits. Bashen and her business have received multiple awards. In October 2003, Bashen was given the Pinnacle Award by the Houston Citizens Chamber of Commerce. Bashen is also the recipient of the prestigious Crystal Award presented by the National Association of Negro Business and Professional Women's Clubs Inc., for achievement in business. Bashen is a frequent lecturer on equal employment opportunity and fair employment practices. She has written numerous white papers and articles in the area of EEO, diversity, fair employment practices, and affirmative action.

Birth Control Patch

The birth control patch, also called the contraceptive patch, can replace a daily birth control pill. Patches are transdermal (applied to the skin) and use estrogen and progestin to prevent egg fertilization. The birth control patch is as reliable as combined birth control pills and is available only by prescription.

Since the first contraceptive came into existence around 3000 BC in ancient Egypt, many inventors have worked to improve contraceptives and birth control over the last 5,000 years. The birth control patch is one such improvement. Invented by Ortho-McNeil Pharmaceutical in 2000, the birth control patch is a small, thin, square, beige patch that looks like a Band-Aid and has a 91 percent effectiveness rate when used correctly. The birth control patch not only provides the benefits of averting pregnancy, but the hormones transmitted through the patch also help with reducing acne, easing painful menstrual cramps, inhibiting bone thinning, limiting iron deficiency anemia, and regulation of one's menstrual cycle, as well as promoting shorter and lighter menstrual periods. The hormones that the birth control patch releases allow cervical mucus to thicken, preventing sperm from reaching and fertilizing eggs. The birth control patch can also inhibit eggs from leaving the ovaries, which is one of the most effective ways to prevent pregnancy.

The birth control patch is waterproof, but it should be applied on dry, clean skin, which allows the hormones to pass from the patch into the bloodstream. The birth control patch has also been known to help with women's sex lives, as they feel more spontaneous by not having to worry whether they took their pill on time. For many women, the patch is preferable to pills because it requires weekly, not daily, attention.

Commercially available since 2002, the birth control patch has made its way into the contraceptive industry by helping women find new ways to control their hormone levels without having to worry about unwelcome pregnancies. With this new form of contraceptive on the market, women can now have more carefree sex live. Although the birth control patch does not protect against sexually transmitted diseases or AIDS, it is a highly recommended birth control that

Planned Parenthood supports and recommends, as it has a low failure rate when used correctly.

Blizzard Entertainment

Blizzard Entertainment is a video game development company, most famous for their influential titles *World of Warcraft* (WOW), *Diablo*, and *Starcraft*. It is widely recognized as one of the most successful video game companies in the world.

The company was founded in 1991 as Silicon & Synapse by Allen Adham, Mike Morhaime, and Frank Pearce, three college graduates. Their first titles, *Lost Vikings* and *Rock 'n Roll*, launched on the Super Nintendo and received relatively positive reviews. In 1994, S&S formally changed its name to Blizzard and successfully shipped *Warcraft*, the predecessor to WOW. After the publication of the *Diablo* and *Starcraft* series, Activision purchased Blizzard in 2008, leading to a merger of the two entertainment giants.

As of 2017, against the norm for entertainment companies, Blizzard had achieved and maintained success in all its franchises and planned to host *Destiny 2* on its game client Battle.net later that year. *Overwatch*, *Heroes of the Storm*, *Diablo*, *Starcraft*, *WOW*, and *Hearthstone* had a combined average of 40 million players online each day.

Cancer Research

Cancer research is the study of cancer to discover its causes and to develop methods of treatment, diagnosis, prevention, and possible cures. Cancer research involves various fields of science, including oncology, epidemiology, virology, molecular bioscience, and others. Cancer research also involves performing clinical trials to test the effectiveness of different cancer treatments. Methods of cancer treatment include surgery, chemotherapy, radiation therapy, gene therapy, hormone therapy, immunotherapy, and combined chemo-radiotherapy.

American scientists have made many major discoveries in cancer research. In 1882, William Stewart Halsted, an American surgeon at Johns Hopkins Hospital, was the first to use the radical mastectomy to treat breast cancer. In 1911, Francis Peyton Rous, an American virologist, discovered that cancer can be caused by viruses when he observed that the Rous sarcoma virus (named after him later) caused cancer in chickens. Rous won the 1966 Nobel Prize in Physiology or Medicine for his discovery. In 1941, Charles Brenton Huggins, a Canadian American physiologist at the University of Chicago, discovered that hormones can be used to treat some types of cancer and won the 1966 Nobel Prize in Physiology or Medicine for his work. In 1947, Sidney Farber, an American pediatric pathologist, was able to cause temporary remissions in children suffering from acute leukemia using an antimetabolite drug called aminopterin. Farber is often called the father of modern chemotherapy as a result of his work.

In 1950, Ernst Wynder, an American epidemiologist, and Evarts Ambrose Graham, an American surgeon and physician, helped to show a link between cigarette smoking and lung cancer for the first time. In 1953, Roy Hertz, an American oncologist and endocrinologist, and Min Chiu Li, a Chinese American oncologist, were the first to completely cure a human solid tumor in a patient with choriocarcinoma using the drug methotrexate. In 1958, Emil Jay Freireich, an

American cancer biologist, Emil Frei III, an American oncologist, and James Frederick Holland, an American physician, were the first to use a combination of chemotherapy drugs to cause remissions and increase the survival rate in adults and children with acute leukemia. Freireich, Frei, and Holland were working as researchers at the National Cancer Institute (NCI), and they used a combination of the drugs methotrexate and 6-mercaptopurine to treat acute leukemia, which had been considered incurable until then.

In 1960, Peter Nowell and David Hungerford, American scientists working in Philadelphia, Pennsylvania, were studying the cancer cells of patients with chronic myelogenous leukemia (CML) when they discovered that the cells had an abnormally small chromosome, which was named “the Philadelphia chromosome.” The Philadelphia chromosome is a genetic defect that is linked with CML, because 95 percent of patients with CML have this trait. This discovery was important because, for the first time, cancer was shown to have genetic causes. In 1976, Harold Eliot Varmus, an American cancer biologist, John Michael Bishop, an American immunologist and microbiologist, and Peter K. Vogt, an American molecular biologist, studied the DNA of normal chicken cells and found a gene related to the oncogene of the avian sarcoma virus. An oncogene is a gene that may cause cancer. Their discovery eventually led to the identification of oncogenes in humans. Bishop and Varmus won the 1989 Nobel Prize in Physiology or Medicine for their work.

A number of American organizations are dedicated to cancer research. One major cancer research organization is the National Cancer Institute (NCI). The NCI was founded in 1937 when President Franklin D. Roosevelt passed the National Cancer Act of 1937. In 1971, President Richard Nixon passed the National Cancer Act of 1971, which gave the director of the NCI the authority to develop a national cancer program that encompasses cancer research all over the United States. The NCI operates a nationwide network of 69 NCI-designated Cancer Centers that concentrate on cancer research and treatment. The NCI-designated Cancer Centers consist of 49 comprehensive cancer centers, 13 cancer centers, and 7 basic laboratory cancer centers, nearly all of which are associated with a university. The NCI receives its funding from the U.S.

Congress—more than \$5 billion each year. In fact, the NCI is the world's largest funder of cancer research. The NCI also manages the National Clinical Trials Network and the Developmental Therapeutics Program. One project that the NCI is responsible for is The Cancer Genome Atlas (TCGA), which was started in 2005. TCGA is managed by the NCI's Center for Cancer Genomics and the National Human Genome Research Institute. The purpose of TCGA is to study the genetic factors of cancer by compiling a database of specific genetic mutations that cause cancer, using the techniques of genome sequencing and bioinformatics.

Another American cancer organization is the American Cancer Society (ACS), which was founded in 1913. ACS is a voluntary health organization with a focus on fighting and preventing cancer, and it receives its funding through charitable donations. ACS's goal is to spread cancer awareness and fund cancer research. Some of ACS's donations go toward providing grants to cancer researchers, including 47 researchers that have won Nobel Prizes. ACS also runs a National Cancer Information Center, which is a call center that serves 1 million callers every year. ACS has over 2 million volunteers working for it and has more than 3,400 local offices. Projects organized by ACS include the Relay For Life, a fundraising event, and the Great American Smokeout, which is an annual day dedicated to getting people to quit smoking.

In 2017, the National Cancer Institute received \$5.389 billion from the U.S. Congress. This money is spent on ongoing investigative cancer research and clinical trials that evaluate possible new cancer cures. American scientists are constantly making new discoveries in the pursuit of a cure for this deadly disease. With more funding and research, scientists may one day find the breakthrough discovery that will put an end to cancer once and for all.

Cassini Saturn Mission

Cassini was launched to explore Saturn, its rings, and its natural satellites on October 15, 1997, by NASA. The data and images taken by Cassini led to numerous discoveries that changed how scientists think about our solar system.

Cassini was the fourth space probe to visit Saturn and the first to enter its orbit. Its mission was meant to last for four years, from June 2004 to May 2008; however, the mission was extended for another two years until September 2010 and was branded the Cassini Equinox Mission. The mission was extended a second and final time with the Cassini Solstice Mission, lasting another seven years until September 15, 2017. On that date, Cassini fell from orbit and burned up in Saturn's upper atmosphere. Overall, Cassini was active in space for almost 20 years, with 13 years spent orbiting Saturn.

Since Cassini began its orbit of Saturn, it obtained 514 gigabytes (GB) of data and also found seven new satellites of Saturn; moreover, Cassini swung by 132 times using Saturn's satellites, and it rotated around Saturn 206 times. It also took 332,000 pictures. Among its discoveries, Cassini found storms on Jupiter and succeeded in supporting the general theory of relativity.

When Cassini swung around Jupiter, scientists measured a frequency shift in the radio waves both to and from the spacecraft as it passed close to the sun. According to the general theory of relativity, a massive object such as the sun causes space-time to curve, which would create a beam from the radio waves. Cassini began a series of radio occultations (events that

Cassini program manager Earl Maize, left, project scientist Linda Spilker, center, and flight director Julie Webster, right, during a press conference following the final plunge of Cassini into Saturn's atmosphere at the Jet Propulsion Laboratory in California, 2017. (Brian van der Brug/Los Angeles Times via Getty Images)

occur when one astronomical object is hidden by another object that passes between it and the observer) to measure the size distribution of particles in Saturn's ring and to measure the atmosphere of Saturn.

When Cassini researched Titan, which is Saturn's moon, it found that Titan has a flow path due to the presence of liquid, allowing scientists to theorize that there could be rain on Titan. Cassini then launched the Huygens probe, a spacecraft sent to search Titan's cloud, atmosphere, and surface in 2005. In 2012, Cassini watched the aftermath of the massive Great White Spot storm that recurs roughly 30 years on Saturn.

Cassini observed the hexagon on the north pole of Saturn for the first time and found two huge polar hurricanes on both its north and south poles. It also found that the hexagon changed from blue to more of a golden color between 2012 and 2016, and there was less blue overall on Saturn between 2004 and 2008.

Cassini's mission ended on September 15, 2017, when its trajectory took it into Saturn's upper

atmosphere and it burned up to prevent any risk of contaminating Saturn's moons, which might have offered habitable environments to stowaway terrestrial microbes on the spacecraft. When Cassini's mission ended, it passed through the gap between Saturn and Saturn's inner rings to maximize the spacecraft's scientific outcome before it was disposed of.

Drake Equation

In 1961, Dr. Frank Drake (1930–) devised the Drake equation, which is a way of estimating the number of communicative extraterrestrial civilizations that may exist in our Milky Way galaxy. Although the equation can be manipulated to a certain extent, it represented the most scientific way of challenging the belief that life on earth was a one-time galactic event. One major legacy of the equation has been a movement to locate radio signals from other planets with the use of innovative technology.

The Drake equation is: $N = R^* \times f_p \times n_e \times f_i \times f_l \times f_c$ $\times L$. N stands for the total number after all of the variables are multiplied. Disagreements over the value of each variable has rendered the value of the equation somewhat subjective. Not surprisingly, those who do not believe that extraterrestrial life exists usually end up with a zero or a very low number for N . In contrast, those who believe that extraterrestrial civilizations exist have determined N to be as high as 5,000. R^* stands for the rate of stars created in our galaxy per year. The National Aeronautics and Space Administration (NASA) calculated this number at six new stars per year.

While some researchers have estimated a higher number for R^* , other researchers have estimated a much lower number. Not all stars have observable planets. Therefore, f_p stands for the fraction of new stars with planets. Based on observations of our solar system, most scientists believe that not all planets are capable of sustaining life. In this respect, n_e stands for the average number of planets that can support life. However, just because a planet can support life, it does not necessarily follow that such a planet contains life. To address this possibility, f_i stands for the fraction of planets that have actually developed life.

Scientists have also observed that not all life forms on earth exhibit intelligence. For this reason, f_l stands for the fraction of planets with life that have developed intelligence. Not all intelligent life forms may have discovered radio waves or may be willing or able to communicate with Earth. Therefore, the fraction of planets with intelligent life willing and able to communicate with Earth is represented by f_c . Finally, even

if a planet contains a thriving civilization, it may be too far away from Earth for its radio waves to reach us. For example, Earth's earliest radio signals have only reached about 100 light years into our galaxy, which is about 100,000 light years in diameter.

Drake founded the first Search for Extraterrestrial Intelligence (SETI) program in 1959. Since that time, various groups, including universities and NASA, have joined the program. Over the years, SETI's desire for better search tools has contributed to the development of innovations in space observation technologies.

e-Book and e-Reader

Michael Hart changed the literary world when he created the first electronic book in 1971. Although the concept for e-books was first patented by Ángela Ruiz Robles in 1949, Hart receives credit for developing the first text available for electronic download and distribution. Over the years, the integration of e-books into society has drastically altered the way we write, publish, retain, and share stories and information.

As a student at the University of Illinois, Hart befriended a classmate working in the campus Material Research Lab who allowed him unrestricted access to the lab's large Xerox mainframe computer. Primarily used for processing data, this computer also accessed ARPANET, an early component of the Internet. Hart's first text was the Declaration of Independence, but typed in all caps as the standard computer format dictated. He then delivered a message via ARPANET announcing that a digital copy of the document could now be obtained. It was the first e-book.

With unlimited access to the computer, Hart set to work, striving to reach the goal of digitizing all available public domain information and making it accessible to anyone. After the Declaration of Independence, Hart digitized the Bill of Rights, the U.S. Constitution, and the Bible. He titled his digital endeavor “Project Gutenberg.” Today, Project Gutenberg continues, thanks to the work of volunteers, and touts a collection of over 50,000 free e-books.

Examining the landscape of e-books in today’s technological society, one can easily observe the far reach of Hart’s initiative. With the advancement of handheld reading devices and apps sweeping the globe, the demand and necessity for digitized information continues to grow. The most popular e-reader, the Amazon Kindle, appeared in 2007, and through creative marketing strategies combined with affordable prices, it quickly soared to the top of e-reader sales. Other notable e-reader devices such as Barnes and Noble’s Nook and the Kobo have tried to keep up with the Kindle, but they can’t compete with the dominance that Kindle holds over the entire electronic book phenomenon. As an already established global provider of services, Amazon has attained a prestigious position in the selling of print books, making its success with selling electronic books seamless and simple.

Devices created for the sole purpose of reading face another threat besides other e-reader competitors: tablets. As society becomes more globalized, tablets have asserted themselves as the favored option for electronic reading. Tablets allow consumers access to multiple functions on one device. A user can easily maneuver between a novel, e-mail, the Internet, and social media with the swipe of a finger. This convenience encouraged the once-in-demand e-readers to adapt and funnel efforts into applications downloadable to tablets and other technologies, such as phones and computers.

The United States accepted the new reading platform faster than any other nation, with publishers and technology titans constantly responding with improved products to enhance the reader’s experience. In 2012, e-books ranked as the top format for adult fiction works. The price of an e-book is considerably lower than the price of a printed work, which has helped propel its success. Affordable pricing combined with its

instantaneous arrival after purchase has helped secure e-books’ top position in the literary world. Statistically, more women utilize e-books than men and are the consumer group most likely to purchase an e-book-compatible device. On average, children and teenagers read more e-books than printed books. However, an outlier for this trend lies with elementary readers, who prefer reading a physical book to reading a digital publication.

The effects of e-books and their distribution are varied. With the digitalization of global society, publications reach more audiences than ever before. Interestingly, citizens of many developing countries acquire technology and mobile devices more easily than physical books. Partly responsible for this access is the Worldreader initiative, which provides tablets and e-readers to schools in Africa to assist in education. Before Worldreader, books arrived by boat, and often, by the time they did, interest in and the relevancy of the publications had expired. Providing e-readers to developing countries enables others to take part in the global communication experience. This increased access propels the spread of information as well as the seeking out of education and engagement in local and international entertainment.

One interesting additional point is that most books released electronically are initially published in English. Citizens of countries where English is not the primary language download and read works in English, ultimately establishing it as the global language. However, many traditional cultures, especially in Europe, have resisted the emergence of e-books, feeling that they disregard and diminish cultural and national identities. Historically, countries have documented important events in books, binding and storing them as a type of memorial intended as a catalog of events for future generations. Some fear that the inundation of society with electronic works will eliminate this traditional, meticulous record-keeping practice.

Piracy has also become a major concern. Although authors benefit when more readers access their work, it also increases the risk of their work being downloaded and distributed illegally. For each digital release of a novel, a duplicate copy appears through an alternative online platform for free download just a few days later. Selective release of titles by territory is one motivation

for illegal downloads. Most commonly outside the United States, a title released by Amazon in one country may not become available in a neighboring country until much later, as dictated by territory. Thus, readers opt for alternative methods of acquiring books. Publishers and distributors continue to research the best way to police the illegal distribution of e-books, while many self-publishers argue that piracy is not the problem that traditional publishing says it is. Many independent publishers argue that piracy does not play a large enough part in book distribution to damage authors and that any book, distributed by any means, will eventually improve author sales.

With a digital literary world, opportunities for self-publishing have developed, and more authors now have a chance to spread their work. Due to self-publishing, title production tripled to 235,000 between 2006 and 2012. The accessibility and freedom of self-publishing enables anyone to become an author and offers countless new stories and perspectives to be shared with the world. To assist the growing population of publishers to distribute their work and connect readers with new titles, sites such as Bowker Bookwire have emerged. Established in 2009, Bookwire is a Web site devoted to circulating independently published works along with other major retailers quickly and reliably to make publications available across a variety of platforms.

The success of an e-book relies on two key factors: availability and discoverability. The more exposure and promotion a title receives results in a wider audience, which places greater significance on online reader reviews. As more titles appear online in the same venue as social media, social interactions and evaluations between readers increase. From a tablet, a reader has the ability to highlight portions of the text and share them on various social media platforms or share reviews of a book recently completed, making reading a more social experience. The popular app Goodreads, owned by Amazon, capitalizes on this trend, attracting over 25 million members who share, recommend, and review titles of both e-books and printed works. The ease with which readers can share their insights on stories via the Internet stimulates important discussions and promotes the global exchange of information.

Despite the great advantages e-books present, many speculate on the serious consequences of their development. For instance, because the Internet world moves so quickly, authors feel pressured to produce mediocre work to keep up with the demand of publishers and readers, and they feel their craft is often compromised in the process. Other studies show that the electronic format of literature encourages readers to skim material, absorbing each page in an *F* pattern: beginning at the top, scrolling, reading another section, and scrolling again; reading only portions of a work. This practice results in a lower comprehension of the content and also affects authors and their writing process as they aim to adjust to the trend. Considering the versatility of many e-book-compatible devices, attention spans are also shorter as audiences find themselves distracted by e-mail, games, and social media during their reading. Not only does this affect authors as they strive to create more enticing story lines, but it also affects teachers as they must construct fast-moving and engaging lesson plans to keep students' attention.

Looking forward, readers can anticipate the introduction of video and audio components to their e-books. Authors and publishers hope the added stimuli will enhance the e-book experience, making it more artistic and interactive. The place that e-books currently hold also sets the foundation for growth of international media by increasing sharing and collaboration around the world.

e-Sports

The term “e-sports” refers to electronic sports, which are public presentations of contests involving players of video games rather than the more traditional physical sports such as football or baseball. E-sports have seen a consistent rise in popularity, with different types of video games entering the pool. Popular video games that have contributed largely to the e-sports pool consist of strategy games such as *Starcraft 2*, multiplayer online battle arenas (MOBAs) such as *League of Legends*, *Dota 2*, *Heroes of the Storm*, and *Smite*. First-person shooters such as *Call of Duty*, *Counter Strike: Global Offensive*, and *Overwatch*, as well as fighting games such as *Marvel vs. Capcom*, *Street Fighter*, and *Super Smash Brothers*. The variety of games played in competitive e-sports competitions allows for many spectators to sit and watch their preferred style of game. E-sports has seen a growing popularity in many industries looking for sponsorship opportunities, due to the many viewers worldwide. In 2015, Madison Square Garden was sold out for the *League of Legends* tournament, while 36 million people streamed it online.

E-sports has adapted into conducting many of the same types of personal tournaments, such as against fantasy leagues, to compete with other individuals. These fantasy leagues consist of professionals from different teams, and depending on their performance, the individual scores points against the professionals and can potentially win money. Many companies provide products for those who watch e-sports as well as those who look up to the professionals in their favorite games—products such as aim assist for controllers and glasses to prevent eyestrain from staring at a screen for long periods. These products have seen an increase in sales worldwide due to the popularity of e-sports. Many of the professional teams involved sell their gear online just like any other professional sport teams, such as clothing, peripherals, and even professional jerseys.

New video games are released constantly, and many are designed with a vision toward competitive play. The most recent game added to the e-sports lineup that has gained popularity in the gaming community is

Overwatch. It is based on teams of six people each who work together to break the other team’s defense. Professionals practice for hours every day to improve their reflexes, awareness, game sense, strategies, and personal skills. Just a year after its initial release, the game set up its second world cup in 2017.

Just as in physical sports such as soccer, nations from across the world prepare their best players to compete with other nations. In the 2016 *Overwatch* World Cup, South Korea took the glory after a well-fought battle with Russia. The event had over 100,000 viewers, and the game had only been out for half a year. Its fan base and the number of professional teams that compete in it continue to grow.

Many disagree, however, that e-sports should be considered sports, since they don’t involve physical activity. Professional e-sports players do take part in mental activity and training, and while moving a mouse may not be as physical as running, professionals still run the risk of injuries to their hands for over-extensive play that may be long term and end their careers as well. Certain television channels, such as ESPN, broadcast about e-sports when major tournaments come up. E-sports is a growing competitive sport that may resemble traditional sports but can look very different. Many don’t see chess or poker as sports either.

E-sports teams and audiences have both grown, and a new sports scene can influence the economy as more products are released, and tournament winnings worldwide may influence currency fluctuations. All one needs is an Internet connection and a computer to pick up e-sports as a hobby. Many games allow costume modifications that fans can apply to their favorite characters. If this is a pay option, it boosts the circulation of currency. It can also increase the fan bases for characters.

Many of these games have categories for casual gamers who want to feel the intensity of competitive play, placing them into ranks that match their skill level. Players can practice in the comfort of their own home and potentially become professional e-sports athletes someday. Colleges across the United States have begun offering e-sports scholarships and creating teams to compete nationally and internationally.

The popularity of e-sports in the gaming community has led to streaming of gameplay for casual gamers to learn from and improve their own play. The United States has officially declared all e-sports professionals athletes, allowing them to receive travel visas to enter and compete in the United States without being citizens. This has paved the way for more professional tournaments on U.S. territory, bringing more exposure to the world of e-sports.

Facebook

Facebook is a U.S.-based social networking site built by Mark Zuckerberg from his idea of connecting people via the Internet. Keeping people connected with their friends and family and other things that they want to be connected to, such as information and entertainment, drives the success of this technology. Facebook as a program learns from its users through various algorithms and continuously adapts to fit a larger, diverse, and constantly growing user base. Facebook supports a hacker culture (individuals who enjoy the intellectual challenge of creatively overcoming limitations of software systems to achieve fresh and smart outcomes).

With headquarters at 1 Hacker Way, Menlo Park, California, and additional offices around the United States and the world, the company employed nearly 14,000 people in 2016. Facebook is the largest cohesive source of communication on the globe. There is an average of 1 billion active users on computers and

nearly the same number was on mobile devices daily as of the summer of 2016. With over 80 percent of its daily users outside the North American continent, registered users have made Facebook as a community more heavily populated than any country in the world.

This icon of technology did not come from a high-tech corporation think tank. Instead, Facebook came out of a dorm room and flourished through an Ivy League infancy. Propelled to the public stage on February 4, 2004, from the campus of Harvard University in Cambridge, Massachusetts, Thefacebook.com, an online directory and social networking community, made it possible for Harvard students to create profile pages containing their personal information and to maintain contact with each other. The only requirements were to have an e-mail address ending in "harvard.edu" and to be older than 18 years of age. Labeled "a Mark Zuckerberg production," the contact page listed:

Mark Zuckerberg: Founder, Master and Commander, Enemy of the State

Eduardo Saverin: Business Stuff, Corporate Stuff, Brazilian Affairs

Dustin Moskovitz: No Longer Expendable Programmer, Paid Assassin

Andrew McCollum: Graphic Art, General Rockstar, and

Chris Hughes: The Secret Weapon, as the organizational side of this enterprise.

Mark Zuckerberg (1984–), the founder of Thefacebook.com who would become the CEO of Facebook, was inspired to make Facebook by his experience with another software program called *Facemash* that he had written earlier at Harvard. As founder, Zuckerberg was responsible for setting the general direction and eventually the product strategy for the company. At the inception of Thefacebook.com, Zuckerberg was a computer science major at Harvard University. Cofounder Dustin Moskovitz (1984–) was his roommate and an economics major at Harvard who served as an early spokesperson for the site, as did Chris Hughes (1983–), who had a very useful ability to predict and visualize what the user might need and also served as customer service representative and spin doctor.

Eduardo Saverin (1982–) managed the business development and sales aspects during Facebook's early years. Andrew McCollum (1983–) was enlisted to help with the site's look and was responsible for the original logo of Thefacebook.com: a picture of a young man's face dotted with binary code. Thefacebook.com helped students at Harvard connect with friends and other people they might find interesting. With the ability to create their own profiles and set their own privacy levels, Thefacebook.com was an almost instant success. While there was more personal information displayed on this site than in previous platforms of its type, people nonetheless were intrigued with this new socialization tool.

From its initial launch, Thefacebook.com became popular as an online directory that connected people through social networks at colleges and universities. In March 2004, Thefacebook.com expanded from Harvard to other elite campuses such as Columbia, Stanford, and Yale. By July of this same year, due to its increased popularity and evidence of commercial viability, the headquarters were moved to Palo Alto, California. In September, the "wall" feature was added to the program, and people could now post messages on profiles that everyone could see. By early December, 1 million people were on Thefacebook, and by May 2005, over 800 college networks were a part of Thefacebook community. September 2005 was notable in that shortly after high schools were added as eligible to participate on the site, the "The" was dropped, and the site officially became Facebook.

Six million users were part of Facebook by December of the same year, while 2006 saw the addition of workplace networks and a news feed to the program. It was not until September 26, 2006, that Facebook as we know it began its meteoric rise to icon status, when it opened its doors and allowed anyone to join. By December 2006, there were 12 million users registered and by December 2007, 58 million people had become active on the site.

The year 2008 saw the introduction of the now iconic "Like" button, the launching of a Spanish-language option, and the creation of an app for the Apple iPhone. Facebook has since acquired other programs that support the initial ideal of inclusion and widened its web of connectedness, such as Oculus,

WhatsApp, and perhaps its most visible, profitable, and engaged app, Instagram, in 2012. 2011 saw video calling and the Facebook for iPad come onto the scene. By 2013, over 100 million people per month were verified as using Facebook on their smartphones. And by April 2015, there were over 40 million active small business users.

Facebook users submit details of their history, demographics, personal likes and dislikes, and billions of photos documenting their lives. Due to the copious amounts of information dispensed to the site and the necessity for adequate storage for it, construction was started on a custom data center in Prineville, Oregon, in January 2010, and it opened on April 15, 2011. There followed additional data centers in Altoona, Iowa (2013), and Fort Worth, Texas (2015), as well as an engineering office in Seattle, Washington, in August 2010.

While claiming the dominant space in the social networking arena, Facebook developed and added technology that furthered its mission of connectivity. A fairly recent term, "citizen journalism," has been a staple of Facebook technology. Citizen journalism sites and publications that wish to distribute user-generated information throughout an online community have found fertile ground on Facebook, often through the news feed. Formerly known as EdgeRank, the algorithm decides which stories are important to individual users. News feed stories are personal and informative.

The Facebook Feed Quality Program is based on surveys of tens of thousands of people throughout the world who are asked to rate their experiences with the information they engage with daily on the site. Stories that are highly ranked receive higher spots in the news feed. This type of algorithm, while targeting user "likes," has also been criticized as having the potential to direct and manipulate user behavior and likes and dislikes outside of Facebook. However, according to Facebook, the algorithms decide who sees what, not the humans behind them.

The popularity of this easy-to-use site continued with membership soaring to 600 million users in January 2010. An additional milestone was reached when in August 2015, a record 1 billion people used the site. As of the second quarter of 2016, Facebook had 1.71 billion monthly active users. This popularity has also

led to Facebook becoming a major corporate entity, grossing over \$1.5 billion in profit in the first quarter of 2016. With a board of directors consisting of some of the giants of innovative technology and media, including the CEO of the Bill & Melinda Gates Foundation, chairman and CEO of Netflix, and a president emeritus of the University of North Carolina, Facebook has matured to having a clear and sturdy corporate structure.

Created as part of the Internet, Facebook grew to virtually and seamlessly integrate with sites outside itself but still within the World Wide Web, providing a flexibility and variability of resources that makes it attractive to users across all walks of life. Reportedly, over one-seventh of the world's population and almost half of people with access to an Internet connection utilize Facebook. Facebook is now available in over 70 different languages and can be found on every continent on the planet. Facebook has fundamentally become entrenched in all aspects of American and global culture.

Gene Patenting

The act of patenting a newly discovered gene allows for unique segments of DNA, which perhaps code for a certain disease or a certain protein, to be owned by

an individual or corporation. In other words, it is the ability to own a gene or gene sequence and the ability to choose what is done with the gene.

The idea of gene patenting is a very controversial subject among physicians and businesses. Most believe it started in 1980 with the trial of *Diamond v. Chakrabarty*, when Ananda Chakrabarty, an Indian microbiologist, created a bacterium that could break down crude oil and desired to patent his creation as a manufactured object. His application was rejected because bacteria are living organisms and therefore cannot be patented. Chakrabarty took the case to the Supreme Court, which ruled in his favor. This case decision was the starting point for gene patenting.

In 1995, Myriad Genetics, wanting to commercialize gene discovery, patented the BRCA1 gene, which is present in all humans but if mutated, it can cause breast or ovarian cancer. After Myriad Genetics obtained the U.S. patent for the BRCA1 gene, the world scrambled to obtain the patent for the other gene involved in these diseases, BRCA2, but in the end, Myriad gained it in 1998.

After obtaining several patents regarding BRCA1 and BRCA2, Myriad sent letters to laboratories around the world, asserting that testing these genes should only be done through either a Myriad laboratory or one that was licensed by the firm. Many countries refused or tried to fight Myriad's control over both patents. The health minister of Ontario spoke out against the patent and publicly refused to honor it. In the United Kingdom, a BRCA2 patent was given to the Cancer Research Campaign, which said that it would not restrict access to the gene.

Myriad still has a strong hold on the patents in the United States and is still the main source of testing for any mutations of these two genes. In May 2009, two groups, the American Civil Liberties Union and the Association for Molecular Pathology, which consists of geneticists, cancer survivors, and pathologists, sued the U.S. Patent and Trademark Office, Myriad, and the University of Utah. Senior Judge Robert W. Sweet ruled that the patents for the genes were invalid on March 29, 2010, saying that a human gene is not an invention. In August 2011, the U.S. Court of Appeals for the Federal Circuit reversed Sweet's decision. On June 13, 2013, the Supreme Court decided that

naturally existing genes and genes sequences cannot be patented. This decision allowed patents for engineered genes, unnatural occurring genes, or complementary DNA (cDNA). Synthetic DNA is made from the molecule that is the framework for making new proteins.

Patenting natural genes has been ruled illegal, yet the patenting of unnatural genes is still a very controversial topic. There are many drawbacks to the idea of gene patenting, but advocates argue there may also be benefits. Gene patenting allows time to investigate new genes, which can lead to breakthroughs. With a patent, a business does not have to worry about competing with others to for discoveries about the patented gene. Gene patenting also encourages more research. The allure of “owning” a certain sequence of genes tends to drive scientists to work harder to obtain such a patent. Gene patents also offer investment opportunities to forward the research of a gene sequence. Gene patenting encourages health competition. It encourages companies to work harder to find cures for diseases so they can profit if another company wants to use that gene. It allows for more open research as companies can bring their findings to the public without the fear of their ideas or research being stolen.

As noted, there are also negatives about gene patenting. It can also slow the progress of research, since the company that owns a certain gene sequence can keep it private, impeding the potential progress from allowing others to study the gene. Patents can also produce monopolies for certain genes. Gene patenting can also slow the appearance of medical results, since samples must be sent only to the company that owns the patent, and the speed of the results returned to the patient depends on that company’s efficiency. Gene patents also raise health care costs because companies that want to use a patented gene must pay for it, driving up prices for everyone.

Genetically Modified Foods

In 1953, scientists first described the structure of DNA, which contains the patterns for constructing proteins in the body. Drawing on these insights, subsequent generations of molecular biologists experimented with genetic engineering, introducing one or more genes into the genome of a species to create traits that did not naturally occur in that species. They achieved rapid advances in genetic modification of organisms, including food plants, in the 1970s and 1980s, with scientists quickly moving from modifying single cells to manipulating the DNA structures of more complex organisms. In 1972, biochemist Paul Berg created the first recombinant DNA molecules by using enzymes to cut DNA strands and introduce new genes into them. In 1973, biologist Rudolf Jaenisch successfully introduced foreign DNA into a mouse embryo.

The legal status of genetically modified (GM) species (also referred to as genetically modified organisms, or GMOs) was initially unclear. In 1980, General Electric attempted to patent a bacterium capable of breaking down crude oil, which the company believed could be used to clean up oil spills. The federal government rejected the request, claiming that living organisms were not eligible for patent. When GE appealed to the Supreme Court, the Court overturned the patent office’s decision, upholding manufacturers’ right to patent GM species. The first GM plant, an antibiotic-resistant strain of tobacco, was produced in 1982, and field trials for herbicide-resistant tobacco plants occurred in the United States and France in 1986.

Reflecting the rapid advancement of the technology, the 1990s brought the commercial distribution of GM food crops. Calgene, a biotechnology company founded in a California garage in 1980, released in

Parents and children protest in Pensacola, Florida, joining a worldwide effort to raise awareness about Monsanto's impact on the food supply and the dangers of GMOs. (Cheryl Casey/Dreamstime.com)

1994 a modified tomato that possessed a longer shelf life and that ripened without softening. Genetically modified soybeans, cotton, squash, and sugar beets (an alternative to cane sugar) were introduced later in the decade. The most successful early GM crop, "BT corn," contained its own pesticide (*Bacillus thuringiensis*), practically eliminating the need to release toxic sprays across wide swaths of land. "Gold" rice developed in 1999 contained enhanced quantities of vitamin A, designed to address the blindness problems plaguing areas with high rice consumption.

GM crops became subject to extensive government review in the United States, needing approval by the Department of Agriculture, the Food and Drug Administration, and the Environmental Protection Agency before they could be marketed to consumers. However, the United States (in contrast to Mexico, China, most of Europe, and several dozen other countries) does not require explicit labeling of GM products once they are distributed to stores for sale. Though attempts in state legislatures to mandate labeling of GM products have historically been unsuccessful, Connecticut in 2013 and Maine and Vermont in 2014 passed mandatory labeling laws, and new requirements were under consideration in a number of other states. Some prominent American professional organizations, most notably the American Medical Association and the American Association for the Advancement of Science, have argued against mandatory labeling on the grounds that it would needlessly alarm consumers.

Many prominent voices spoke out in favor of GM crops. Foremost among them was former president Jimmy Carter, who established the nonprofit Carter Center after leaving office and set about upon a number of humanitarian ventures, including teaching methods of increasing crop yields to farmers in sub-Saharan Africa. Carter was highly supportive of using genetic engineering to breed plants with improved yields, and strains designed to resist drought were also especially useful in hot tropical countries. Also enthusiastic was biologist Norman Borlaug, who had himself cultivated and developed high-yield, disease-resistant wheat crops in the 1940s and 1950s that improved food security in countries like Mexico, Pakistan, and India. Borlaug was excited about the potential of GM crops as the next step in ending world hunger problems.

Nonetheless, GM foods received criticism on a number of different fronts. The first objection was that more research needed to be conducted before GM foods could be deemed safe for large-scale introduction to already-existing ecosystems. Britain's Prince Charles, for example, argued in 1999 that it was not yet fully understood how GM crops would affect complex, interdependent ecosystems once they became part of them, and that altered genetic material could not be removed from the environment once introduced if some unwanted side effect resulted. Already observers

had noticed that, while BT corn was effectual at killing the pests that antagonized it, it also eliminated many beneficial insects. Furthermore, the process of natural selection meant that over time, insect species would adapt, with the remaining individuals evolving to become pesticide-resistant. What effect would occur once birds ate the insects and the GM material made its way up the food chain was as yet impossible to predict. Bees, too, were likely to cross-pollinate pesticide-resistant crops with unmodified plants in the same area, again with unknown results. The environmental group Greenpeace made a similar argument as Prince Charles, invoking the “precautionary principle” to call for more extensive research on GM crops and to ask the Environmental Protection Agency to suspend approval of BT corn. Some philosophically minded critiques warned of the danger of “playing God” by immorally manipulating genetic material, but proponents replied that genetic engineering was simply an extension of the human modification of the natural world that had been occurring for millennia.

GM foods’ effects on humans themselves also came under scrutiny. One strain of modified rice had been engineered to reduce its levels of glutenin, which made it more suitable for brewing the Japanese rice drink sake. However, the reduction in glutenin unexpectedly encouraged the rice to develop higher levels of compounds called prolamines, which can cause an allergic response in humans. A controversial 1999 study claimed that GM potatoes fed to rats had damaged their digestive tracts, and in 2011, researchers in eastern Quebec found evidence that BT toxins were being passed from human women to fetuses (though proponents pointed to hundreds of other studies showing no negative health effects to humans from eating GM foods and replied to the 1999 study by noting that *any* rat fed solely on potatoes would suffer from protein deficiency as a result).

Another line of criticism involved GM foods’ patentability. Patenting GM products was essential for protecting corporations’ research investments, but it disrupted the normal processes of farming. Since virtually the beginning of human history, farmers had saved a portion of the seeds from each year’s crop to plant the next season. But now farmers had to buy new seed every year from the manufacturer, making GM crops into one of the world’s most profitable commodities.

Monsanto, an agrochemical company that emerged as the leading American producer of GM foods (and which acquired smaller companies like Calgene), compelled farmers buying its seeds to sign contracts allowing the company to test crops in future years to prove that the farmers were not buying one batch of seed and then reproducing the product themselves. Farmers caught violating patent rights in this manner by not buying new seed every year were sued by the hundreds. Monsanto later developed a gene technology known as “the Terminator” that rendered crops sterile, preventing farmers from replanting them without the need for investigations and litigation. The legal protections for GM crops generated broader concerns that only rich, developed nations would be able to afford GM foods, widening the wealth gap between the developed and developing worlds.

Added to this particular concern was the insistence that GM proponent Norman Borlaug’s own innovations themselves, which had produced high-yield wheat cultivars through breeding and natural selection alone, were sufficient to solve the problems of hunger in the 21st century. Ongoing famine problems were not related to a lack of food, critics said, but political instability and widespread corruption in developing nations. GM crops were thus not needed as a solution to world hunger, these analysts claimed, and they accused GM companies of using the famine-reduction justification to shield themselves from criticism of their business practices as well as GM crops’ potentially harmful ecological effects.

Some radical environmental groups like Greenpeace and Friends of the Earth, along with other anti-GM activists, engaged in sporadic acts of vandalism to disrupt research. Activists set the biotechnology laboratory at Michigan State University on fire in 1999, and protestors have vandalized other research sites in the United Kingdom, Australia, and other countries across the world. In May 2013, the “March against Monsanto” movement organized protests in Portland, Oregon; Los Angeles, California; Buenos Aires, Argentina; and other cities.

In spite of these multiple layers and forms of criticism, GM crops encountered no widespread opposition in the United States, and by 2000, they were being sold in grocery stores around the country without

labeling. In 2013, foreign governments that distrusted American corporations, however, opposed the import of GM foods to their countries, and the 2000 Cartagena Protocol signed in Montreal, Canada, required export shipments of food to identify whether or not they contained GM foods and allowed importing countries to reject shipments on that basis alone.

Google

Google began at the nation's greatest technical incubator, Stanford University, as a research project by two PhD students—Larry Page and Sergey Brin. Work on what would become the Google search engine started in 1996. The project was called the Stanford Digital Library Project (SDLP). The project was originally funded by a number of government agencies, including the National Science Foundation. It developed an early search engine called BackRub. It was not the first; in fact, Excite, WebCrawler, Lycos, Infoseek, and OpenText were already on the Internet. Carnegie-Mellon University's Lycos was then the most-used search engine on the browser company Netscape's list, even though Infoseek was the default search engine on Netscape. These early search engines were viewed as software to be licensed or sold, not as moneymaking ventures. The rise of Google was due to its business model rather than its technological advantage.

The history of the search engine is almost as old as the computer itself. The source of commercial search engines can be traced to Stanford University long before Google. The Internet directory Yahoo was formed by two Stanford students, David Filo and Jerry

Yang, in 1994 and was incorporated in 1995 with \$2 million in venture capital. Yahoo functioned as a full-service Internet provider with a search engine licensed from others. Even earlier, a group of Stanford undergraduates had developed a search engine using statistical analysis of word relationships in 1993. The software was released and evolved into the company known as Excite. At the time, no true business model for making money from search engines had emerged except to sell to, license, or develop an Internet service. In many cases, search engines were offered for free by Internet providers. Lycos was a major search engine developed by Carnegie-Mellon University students; it was used freely on the Internet but also developed into a service company. By the late 1990s, new ideas to make money from search engines emerged.

In 1996, AltaVista and Inktomi Corporation were advancing search engine technology. AltaVista was the first to allow for natural-language queries as well as advanced search methods using Boolean logic. Inktomi had a search engine known as Hotwire, which included the best technology and the beginning of a new business model. A great deal of search engine software was available, but the commercial rewards for further development seemed few. Inktomi saw the possibility of commercial gains by charging a flat or recurring fee for commercial Web sites (paid inclusion). While Inktomi pioneered paid inclusion, the market was not yet big enough to support it. Some search engines were using pop-up advertisements with limited success.

In 1998, Bill Gross, founder of Overture (initially known as GoTo.com), developed a pay-per-click business model for his search engine. The idea was that advertisers paid a fee when their Web sites were clicked on after they were found via an Internet search. These agreements are known as sponsored ads. The idea generated a great deal of appeal to advertisers, who were used to broadcast advertising on television. Pay per click assured that members of the audience were being individually targeted. Google would eventually adopt this model and expand its application to targeted audiences. However, the success of Overture initially showed Google and potential investors the possibility of making money with search engines.

In August 1998, Google got a loan from Stanford entrepreneur and cofounder of Sun Microsystems, Andy Bechtolsheim. The next month, the company formally incorporated as Google Inc. and operated out of a garage. The name came from the term “googol,” representing the number 1 followed by 100 zeros. Google quickly gained a reputation as a better search engine than Excite and HotBot. The company moved to the now-famous incubator at 165 University Avenue in Palo Alto. The focus was to build user loyalty and technical superiority. It attracted venture capitalists such as Kleiner Perkins Caufield & Byers and Sequoia Capital. Sequoia had already made profitable investments in Apple Computer, Atari, Oracle, and Cisco. Google was able to get \$25 million from the two, but Sequoia required the hiring of a CEO and a fully developed business model. Sequoia clearly brought the business discipline needed for Google to become dominant. The model was based on selling key search words to advertisers using a combination of bids and click-through charges. Google continued to rise in stature, and eventually America Online chose Google as its search partner, followed quickly by Yahoo. However, it would take another two years for it to fully overcome rivals such as Overture. The competition of search engines led to the incorporation of technology and marketing in Google AdWords.

The unique and specialized advertising model of Google AdWords revolutionized the marketing business model. AdWords is a pay-per-click system that ranks or orders search results for sponsored links. How much the advertiser ultimately pays depends on bidding on per-click rates based on keywords, and on a quality score. The quality score is a complex calculation based on historical click-through rates, relevance of keywords, the advertiser’s account history, and other relevance factors. In addition, Google added location-based targeting and other frequency factors. By 2003, Google had established itself as the dominant search engine and had moved aggressively into other areas. Google went public in 2004 and controlled over 80 percent of worldwide searching. In retrospect, more than any other company, Google commercialized the Internet and took real advertising dollars from other media such as television and radio. The advertising dollars continue to attract new entries into the

search engine market. By 2005, Google had a market value of over \$50 billion. By 2010, even Microsoft had entered the competition with its Bing search engine.

Google Earth

Commonly referred to as the digital globe, Google Earth is a 3-D representation of Earth constructed with satellite imagery. It was created in 2001 by Keyhole Inc. and obtained by Google in 2004. Since its release, Google Earth has added many features to enhance the digital navigation such as street view and outer space exploration.

Street view allows users to zoom into thousands of cities worldwide. Deep ocean floor areas and celestial bodies can also be observed. This permits one to see the world without the need to travel. Another service that Google Earth has is providing the user with information about certain locations such as landmarks. This feature serves as a guide to explore and understand the planet. Its multifaceted ability attracts a wide range of users because it can be used for fun and entertainment, but it also is a source of knowledge. For example, Google Earth can help students improve their spatial thinking and acquire critical technology skills. While most agree that Google Earth is a useful tool, some claim that it threatens privacy. Despite these allegations, Google Earth continues to innovate its platform and produce new versions.

Grandin, Temple (1947–)

Agricultural scientist, spokesperson for autism, and bestselling author, Temple Grandin innovated designs for livestock equipment at feedlots and slaughterhouses. Her system kept the animals calm while producing higher quality meat and reducing accidental deaths and cruelty. She discovered these concepts because her autism made her thinking process different from that of most people. She has written numerous books on both animal behavior and autism.

Temple Grandin was born on August 29, 1947, in Boston, Massachusetts. She was diagnosed with autism at two years old and did not talk until she was four. At the time, autism was considered an infantile schizophrenia caused by a lack of maternal care. The recommended treatment was to put her in a mental institution, which her father, Richard Grandin, supported. Her mother, Eustacia Cutler, disagreed. Her parents divorced, and Cutler sent her daughter to speech therapists, enforced rigid manners at home, and encouraged her to interact with people.

Autism is still not very well understood. It is a genetic disorder that affects the brain's development by forming stronger connections to the brain's analytical centers. At the same time, weaker connections are formed to the brain's social centers. The net effect is that an autistic person may be able to process information at a higher level than a nonautistic person but has poor social skills. Temple Grandin is a visual thinker, but as a young woman, she often misinterpreted social cues.

In 1966, Grandin enrolled in Hampshire Country School in Rindge, New Hampshire, a boarding school for children with special needs. Her science teacher, Bill Carlock, took a special interest in helping her. She then decided to study psychology at Franklin Pierce University so that she could understand people better.

In the summer between high school and college, Grandin lived with her aunt on a ranch in Arizona.

Grandin observed cowboys prodding cattle down an enclosed path into a squeeze chute, a device that restrains a bovine animal between two metal bars. The cattle were distressed as the cowboys prodded them into the chute, but as soon as the chute closed down on the animal, it calmed down instantly. When Grandin started college, she built a machine similar to the cattle chute for herself. With the pull of a lever, two padded panels would clench her sides and hold her. When the university discovered this, it misinterpreted the device as a sexual object and promptly removed it. Grandin wrote a well-researched paper on her results, proving that the device had helped her, and the school allowed her to keep it.

Next, Grandin pursued a master's degree in animal science at Arizona State University. On a field trip to a nearby feedlot, she noticed that the cattle used different kinds of mooing and were sometimes visibly in distress. The cattle tended to injure themselves whenever a handler approached, and a few of them died each week before they could be slaughtered for market. As a result, the feedlot was losing thousands of dollars every week. For her master's project, Grandin decided to explore cattle behavior and figure out how to reduce fear in the livestock.

After graduating from Arizona, Grandin continued to investigate feedlots and slaughterhouses. She published papers in prominent agriculture journals like the *Western Livestock Journal*. Meat-processing companies started to ask her to redesign their operations, and Grandin made a living as a consultant for companies such as McDonald's, Wendy's, and Burger King.

In 1981, Grandin went to a convention hosted by the Autism Society of America. She was the only person there with autism who could easily talk about her experience. As a result, people wanted to hear her speak about autism. Grandin became prominent to the American public when Oliver Sacks wrote about her in his book *An Anthropologist on Mars*. Grandin began to lecture and write books about autism as well as animal behavior.

Temple Grandin now has a PhD in animal science and has written hundreds of scientific papers on livestock handling. She has also written numerous books and articles on autism, and she is often on tour to raise awareness and educate people about different kind of minds. She is currently teaching at Colorado State

University in Fort Collins, Colorado. In 2010, HBO made a biopic about her life titled *Temple Grandin*.

Hawking, Stephen (1942–2018)

Stephen Hawking's brilliance and popularity can easily be identified as nearly equivalent to that of Darwin, Newton, or Einstein. Some of his greatest achievements include a reinterpretation of black holes, analyzing the beginning of time and space, and popularizing science. Hawking presented a theory in 1974 that was so radical, what it described would be later recognized as "Hawking radiation." Hawking argued against the norm and claimed that black holes emitted energy. This point—although seemingly insignificant—brought key concepts of classical and quantum physics together, reshaping the way scientists see the universe. In 1983, Hawking worked with James Hartle to propose yet another theory: that the universe has no physical boundaries. In 1988, Hawking published *A Brief History of Time*, introducing readers to the science behind black holes, the Big Bang, and the rest of his major theories. The book became a worldwide sensation. Offered in 40 different languages, it eventually sold up to 10 million copies.

Stephen Hawking was born on January 8, 1942, in Oxford, England, into a well-educated family. Hawking didn't always excel in his first years of school despite being recognized as its "Einstein." At age 17, he attended the University College, Oxford—his father's alma mater. After three years at Oxford, he was awarded a first-class honors degree, a condition he needed to meet for his future academic work at the University of Cambridge, where he studied cosmology. Though he was seemingly a difficult student, the

examiners who awarded him his degree recognized immediately that Hawking was cleverer than most of them. He fell into depression within the first year of graduate school soon after being diagnosed with amyotrophic lateral sclerosis (ALS). Hawking had lost his sense of purpose, regaining it only with the encouragement of his supervisor, Dennis William Sciama. Hawking's reputation developed after he challenged the work of astronomer Fred Hoyle. In March 1966, he received his degree in applied mathematics and theoretical physics, emphasizing general relativity and cosmology.

In his career, Hawking explored the singularity theorem and developed the second theory of black hole dynamics. In 1973, he started studying quantum gravity and quantum mechanics. As he went along, Hawking regularly engaged in "scientific wagers" (scientific debates) with other scientists. Scientists don't normally achieve celebrity status, especially in their own lifetimes, but Stephen Hawking is one of the handful who have broken that mold. Scientists whose ideas opposed his openly and continuously criticized him, complaining that his status gave him the unfair advantage of "instant credibility."

From 1979 to 2009, Hawking was the Lucasian Chair of Mathematics, a mathematics teaching position at the University of Cambridge, England. This position is recognized as one of the most prestigious academic posts in the world. Its former holders include Isaac Newton and George Stokes. After retiring from his post in 2009, he accepted a Distinguished Research Chair at the Perimeter Institute for Theoretical Physics in Waterloo, Canada. In the same year that he retired, he was awarded the Presidential Medal of Freedom. This is the highest civilian award in the United States.

In 1983, an American physicist by the name of James Hartle developed a proposal with Stephen Hawking at the University of Chicago. Dubbed the "Hartle-Hawking state," this project was carried out to try to explain the beginning stages of the Big Bang theory. It concluded that the universe had no initial boundaries in time or space at all.

In 2017, Hawking warned that humans needed to colonize the moon or another planet within the next 100 years or risk the threat of extinction, shortening his earlier deadline for interplanetary colonization from 1,000 years. He founded his warning on the

dangers from nuclear war, global warming, genetically engineered viruses, and artificial intelligence. In the same year, Hawking criticized the Trump administration for its treatment of government scientists, such as when the U.S. Environmental Protection Agency and Department of Agriculture received orders to remove Web pages from their sites, reportedly even having to submit their reports to Washington for approval. After his open critique, Hawking feared that he would be banned from the United States.

Many believe that Hawking's iconic side has overshadowed the physicist that he really was. In the mass media, nothing said in Hawking's monotonic robot tone was without near-instant credibility. The presumption was that Hawking was an undeniable source of wisdom. Regardless of his genius, he was capable of making mistakes just like any other human being. Plenty of people robbed him of this aspect of his humanity because of his inspiring story. As a whole, society is still uncomfortable with disability and is fascinated with the idea that someone so disabled could be so intelligent.

Since the 1990s, Hawking participated in fundraising activities as a role model for disabled people. In 2014, he accepted the ALS/Ice Bucket challenge but had to have his children take it on his behalf due to his pneumonia.

Hubble Space Telescope

While earthbound telescopes have helped astronomers investigate the mysteries of the universe since Galileo first used one in 1609, they have all shared a

significant limitation. Telescopes need to penetrate the earth's atmosphere, which interferes with the light coming from distant objects that they attempt to see. A radical 20th-century solution was to place a telescope in low-earth orbit, thus eliminating atmospheric distortion and promising views of the universe vaster and more detailed than any before. The most notable of these was the Hubble Space Telescope (HST), which NASA launched in 1990. Since that time, the HST has become one of NASA's longest missions, and also one of its most successful, returning hundreds of thousands of photographs that have reshaped our understanding of the universe. Most significantly, it has played a critical role in enabling scientists to identify quasars, detect the existence of dark energy, and determine the age of the universe. Hubble has seen galaxies 12 billion light years from Earth, and astronomers refer to this area as the Hubble Ultra Deep Field (HUDF). The telescope is considered to be one of the most productive scientific instruments ever constructed by humankind.

While the HST is the unquestionable champion of orbiting telescopes, it is not unique. One of the first large telescopes was the Orbiting Astronomical Observatory (OAO). Specifically, the observatory's main function was to map and study the emission and absorption characteristics of the sun, stars, planets, and nebulae, along with various interplanetary and interstellar events. Launched in 1968, the total observatory, including its onboard experiments, weighed 4,450 pounds (in contrast, HST weighs 24,490 pounds). Four years later, NASA successfully launched another OAO called Copernicus, and it returned data for over nine years, which was twice as long as the previous orbiting telescope.

After OAO, the next large telescope was the High-Energy Astronomy Observatory (HEAO). The objective of this new class of spacecraft was to locate, identify, and analyze celestial high-energy radiation sources, including pulsars, black holes, neutron stars, and supernovae. There were three HEAO telescopes launched—in 1977, 1978, and 1979.

During this period, NASA began planning for an even more powerful orbiting telescope. This became the Hubble Space Telescope, named after Edwin Hubble (1889–1953), a pioneering American astronomer

most noted for demonstrating that the universe is expanding. At 43 feet in length, it continues to orbit 347 miles above the earth with a velocity of 4.7 miles per second. Goddard Space Flight Center in Greenbelt, Maryland, is the NASA center that manages the mission.

One of the remarkable aspects of the HST is that NASA has been able to service it while in space. Immediately after the HST entered orbit, the first images it sent back were blurry. Scientists discovered that the primary seven-foot mirror had a “spherical aberration” that was just one-fiftieth the width of a piece of paper. NASA planned for nearly a year to send astronauts via a space shuttle to repair it in orbit with complex space walks that riveted the attention of the American public. Though it was one of its most complex missions, it was successful. The space shuttle visited the HST four more times between 1993 and 2009 to make repairs and upgrade its components.

Over 4,000 astronomers and cosmologists have used data from the HST to produce more than 11,000 scholarly articles. Its life span is limited, as the Earth’s gravitational pull will cause it to descend into the atmosphere sometime after 2019.

Since the HST first began operating, NASA has launched other orbiting observatories. In 1995, it launched the Solar & Heliospheric Observatory (SOHO) with a mission to exclusively study our sun. In 1999, the Chandra X-ray Observatory became the most powerful x-ray telescope in the world, enabling astronomers to study gas clouds, particles attracted by black holes, and quasars. In 2003, the Spitzer Space Telescope began focusing on infrared radiation that galaxies, black holes, and comets emit. In 2003, NASA’s Galaxy Evolution Explorer (GALEX) let astronomers investigate the formation of galaxies. Two other space telescopes concentrate on the phenomenon known as gamma ray bursts (GRBs). These are the most powerful known explosions in the universe and are important in better understanding spinning pulsars, black holes, and dark matter. The first of the GRB telescopes launched in 2004 and was named the Swift Gamma Ray Burst Explorer. Four years later, the Fermi Gamma-Ray Space Telescope joined it in orbit. Finally, in 2009, NASA launched the Herschel Space Observatory and the Kepler Mission.

Herschel lets scientists explore the infrared spectrum to look for distant water and the formation of stars. Kepler’s central mission is finding planets similar to Earth within our Milky Way galaxy.

Taken together, the HST and the other space telescopes have resulted in a revolutionary expansion of our knowledge about the universe. Some speculate that humanity has learned more about the universe since the 1970s than in all of history prior to this era combined. There is much more to learn, and the James Webb Space Telescope represents the next generation of orbiting telescopes, with an anticipated launch date in 2018.

Human Genome Project

The Human Genome Project, or HGP, was a research effort to determine the sequence of the human genome and to understand all the genes of human DNA. It was international in scope, involving numerous laboratories and associations of scientists around the world and received public funding from the United States of \$200 million per year via the National Institutes of Health and the Department of Energy. The project formally started in 1990 and finished in 2003. The completion of the Human Genome Project was a huge

milestone in understanding how our genes help determine who we are. The project was largely complete in 2000, when 85 percent of the human genome was decoded, and it ended in 2003 with 99 percent of the genome decoded.

The Human Genome Project opened up many different branches of science, helping us understand different types of diseases, viruses, and mutations in the human body. This alone helps scientists develop more medicines to cure patients. Along with the understanding of the genome, though, the HGP also promoted fear of the power that scientists had with such knowledge.

The HGP officially began in October 1990, but its origins go back to the mid-1980s, when three scientists, Robert Sinsheimer, Renato Dulbecco, and Charles DeLisi, independently came up with the idea of sequencing the entire human genome. Their ideas found supporters in a number of prominent biologists and geneticists. Then, in 1986, committees were established to study the feasibility of a publicly funded project to sequence the human genome. DeLisi outlined a broad plan for the project, and funding eventually enabled it to launch.

The HGP was included in President Reagan's 1988 budget submission and was ultimately approved by Congress. DeLisi had befriended Senator Peter Domenic, chair of the Senate Committee on Energy and Natural Resources, and Congress added a comparable amount to the National Institutes of Health budget.

The Human Genome Project's main goal was to map our genes and sequence only euchromatic regions of the genome—about 90 percent of it. Mapping would eventually reveal the position and spacing of the then-predicted 100,000 genes in each of our cells; sequencing would determine the order of the four base pairs of the nucleotides that compose the DNA molecule: A (adenine), T (thymine), C (cytosine), and G (guanine). While in the process of sequencing the human genome, scientists identified genes for cystic fibrosis, neurofibromatosis, Huntington's disease, and an inherited form of breast cancer.

In addition, the project decoded the genome of the bacterium *E. coli*, a fruit fly, and a nematode worm, to study genetic similarities among species. The HGP team also found out that the human genome has

approximately 3.3 billion base pairs. With the sequence now known, the next step was to identify the genetic variants that increase the risk for common diseases like cancer and diabetes. The key findings were that there are approximately 20,500 genes in human beings, and the same range in mice. Scientists also found that the human genome has significantly more segmental duplications than had been previously suspected. Last, when the draft sequence was published, fewer than 7 percent of protein families appeared to be vertebrate specific.

Since the complete sequencing of human DNA, many controversial topics have arisen about it. With public access to the human genome, many ethical questions presented themselves, such as those about genetic determinism, cloning, and stem cells. Many ethical issues revolve around choosing the genes of offspring. Is it acceptable for parents to handpick genes they would like for their children? The same issue occurs for cloning and stem cells. Some believe that some genes may cause people to sin or commit crimes, or that genes may determine sexuality. One of the worst fears that the HGP brought up was about genetic modification. Scientists were already genetically modifying foods, but the general public has feared that scientists could modify behavior and other things that define us as human.

The Human Genome Project has brought new understanding of the human genetic sequence that makes up who we are. It is described as one of the most significant events in human history—as historical as the moon landing.

Hybrid Vehicles

A hybrid vehicle is any vehicle that utilizes at least two different propulsion systems. Hybrid vehicles can take many forms, from aircraft and watercraft to trains and buses. Power sources can range from something simple, like pedaling, to more complex sources, such as hydrogen-based fuel. However, the most common type of hybrid is the hybrid electric vehicle (HEV) automobile. HEVs still use an internal combustion engine (ICE), but it works alongside an electric motor to achieve greater efficiency while saving fuel costs and reducing damage to the environment.

Contrary to common belief, hybrid vehicles are not new. They have been around for over 100 years. The first hybrid car, called the “Semper Vivus,” was created in 1900 by an Austrian engineer named

Ferdinand Porsche. However, it was not until the 1990s that hybrid cars entered the commercial market. In 1997, the first Toyota Prius was introduced in Japan. Shortly afterward, in 1999, the Honda Insight was released, and it was the first hybrid car available in the United States. The following year, the Toyota Prius went on sale in the United States, and by 2002, there were three different hybrids available.

More companies wanted a piece of the emerging HEV market, so many of the major automakers released their own hybrids, including U.S. manufacturers such as Cadillac, GMC, Chevrolet, Ford, and Honda. HEV sales history reveals a trend that follows gasoline prices. For example, in 2013, the average gas price rose above \$3 per gallon; at the same time, the market share of new hybrid car sales peaked at 3.19 percent. As gasoline prices went down, so did HEV

An electric vehicle charging station near San Francisco's city hall in August 2010. That month the Bay Area Air Quality Management District set aside \$5 million to increase the number of electric car charging stations to 5,000 around the Bay Area. (Justin Sullivan/Getty Images)

sales. The United States has the second-highest level of HEV sales in the world, following Japan. Through 2016, reported sales exceeded 4 million units in the United States alone and over 11 million worldwide.

There are at least three different types of HEVs: plug-in, full, and mild. Although each type has an ICE and an electric motor, their functions differ. Plug-in hybrids, like the Chevy Volt, are the only type that can be charged externally. As the name suggests, they can be plugged into a power source at home or a public charging station. Out of the three types, plug-in hybrids feature the largest battery. They can reach highway speeds and travel tens of miles using only the electric motor. A full hybrid, like the Toyota Prius, has the option to run solely on battery power at lower speeds and distances. They typically have a large battery and motor, along with a sophisticated power-blending system. Mild hybrids, like the Chevrolet Silverado Hybrid, cannot drive solely on the electric motor because it is too weak. Instead, it turns off the ICE and switches to the electric motor in specific situations, like braking, coasting, or idling.

Modern hybrids fuel up with gasoline and are operated just like any other conventional automobile. The HEV system balances energy flow between the ICE and electric motor without any user intervention. To provide the electric motor with sufficient power, hybrids have a large motive battery separate from the auxiliary battery that we see in conventional cars. Usually, the motive battery is based on nickel-metal hydride (NiMH), but newer HEVs are increasingly switching to lithium-ion (Li-ion) batteries. With the exception of the plug-in hybrid, which can be charged by an external source, all HEVs recharge the motive battery in a similar fashion. The primary energy source comes from the ICE, which charges the motive battery whenever it is low. Another key trait is energy regeneration. Anytime the vehicle is in motion and the gas pedal is released, also known as “coasting,” the electric motor captures energy from the momentum. Last but not least, when the brakes are lightly applied, regenerative braking engages to capture additional kinetic energy.

There are several benefits that make hybrids a popular choice. With conventional vehicles, only a fraction of the fuel energy translates into physical movement—in comparison, HEVs are extremely efficient. With hybrids, simply driving downhill will charge the

batteries, and up to 90 percent of the energy in the batteries can be converted into movement. This means that HEVs can be several times more efficient and cheaper to run. Hybrids are also environmentally friendly. Although they run on gasoline, their emissions are substantially lower. In most cases, the HEV’s combustion engine does not need to run when the vehicle is stationary. Conventional vehicles forgo a huge amount of energy during coasting and braking. HEVs, on the other hand, are able to recycle much of this energy by storing it in the batteries. In addition, it has been reported that thanks to regenerative braking, their brake pads last several times longer. Hybrids are known for their outstanding fuel economy, which can benefit entire locations and not just individuals. For example, HEV fuel economy can help island communities to lower their reliance on diesel imports. Certain models, like the 2016 Chevrolet Volt, can get up to 53 miles per gallon.

Hybrid vehicles have their disadvantages. HEVs perform their best in moderate climates, which is probably why they sell the most in places like San Francisco. As for people living in extreme climates, hot or cold, they report decreased performance and loss in range. Another disadvantage is the higher maintenance and repair costs. Private mechanics can offer competitive prices, but they are not always familiar with the hybrid system. If a vehicle breaks down, it may need to be taken to a pricey dealership.

The future of hybrid vehicles looks bright. Fossil fuel is a nonrenewable energy, and despite fluctuating prices, it ultimately goes up in cost. As clean air laws grow stricter, demand for hybrids and other low-emission vehicles is expected to rise. Hybrid technology and components are continuously improving. Currently, lithium-sulfur batteries are being tested. Compared to lithium-ion, lithium-sulfur batteries have superior energy density and can be produced at a much lower cost. When this technology matures, it will be a massive boost for the HEV industry. The battery price has already dropped to \$150 per kilowatt-hour (kWh). A price below \$100 per kWh is believed to be the tipping point where demand for hybrid vehicles will surpass the demand for conventional vehicles.

Hypertext

Hypertext refers to text that is displayed on electronic devices like computer screens and enables a user to immediately access other informational platforms. Hypertext is used by accessing hyperlinks by touch screen or mouse click. Hypertext allows easy access to large amounts of information on the Internet. In fact, Web pages are written in HTML, which stands for “hypertext markup language.” Hypertext can also give access to the abundance of things like data tables, videos, and images across Web site platforms.

Hypertext connects all of the information available through links enabling the user to navigate through progressive levels of information. Hypertext is typically in one of two forms—either static or dynamic. Static hypertext is constant and has a set platform with concrete formatting. Dynamic hypertext, on the other hand, constantly morphs due to user interaction. This includes progressing levels of intricacy and shifting platforms of information. Both forms have their advantages depending on the type of information being accessed.

The person most often associated with hypertext is American Ted Nelson, who coined the terms “hypermedia” and “hypertext” in 1963. He is considered the visionary behind the modern technology of hypertext used across devices today. Theodore Holm “Ted” Nelson was born on June 17, 1937, in Chicago, Illinois. He is the son of two successful Hollywood parents—movie director Ralph Nelson and actress Celeste Holm. He received a bachelor’s degree from Swarthmore College in 1959. He received a master’s in sociology from Harvard in 1963.

Nelson dreamed about creating a flexible system to access all of the world’s knowledge. His goal was a more accessible database of information that could be easily maneuvered through and cross-referenced. He presented the concept of hypertext in his book *Literary Machines* in 1980, in an overview of the hypertext project Xanadu. Hypertext has revolutionized how we access information every day. The most recognized implementation of hypertext is in the World Wide Web. Nelson’s system of hypertext is of two-way links, which preserves the context of information.

In 2002, Nelson received his doctorate in media and governance from Keio University. In 2010, he published an autobiography called *Possiplex*. Nelson has made many appearances and spoken at major tech conferences. A summary of his work appeared in the film *Lo and Behold* (2016).

International Space Station

The International Space Station (ISS) is a hybrid science, technology, and commerce laboratory in Earth’s orbit. Unlike other space station ventures that were undertaken in competition during the Cold War (1945–1989), the ISS is a product of international cooperation that took place over many years. The desire to scientifically explore the universe with the use of the ISS has also spawned technological innovations.

The idea of habitable space stations originated in 19th-century works of science fiction. For example, in 1869, Reverend Edward Everett Hale envisioned an orbiting “brick moon” capable of sustaining humans in space. In the 20th century, rocket scientist Wernher von Braun popularized a novel design for space stations. Braun believed that humans would need gravity to survive in space, and he proposed creating artificial gravity through the use of a rotating wheel design. By the 1950s, science fiction magazines, books, and

motion pictures portrayed space stations as rotating wheels.

After the Soviet Union launched Sputnik I (the first man-made orbiting satellite) in 1957, the Cold War competition between the Soviet Union and the United States grew to include a space race. In 1969, the United States declared victory in the space race after American astronauts became the first humans to set foot on the moon. Although the Cold War continued for another 20 years, after the U.S. moon landing, the Soviets refocused their space program on creating space stations. The Soviet's first space station, Salyut 1, orbited Earth in 1971. Without artificial gravity, three Soviet cosmonauts in each mission rotation worked for months in a cylindrical space laboratory with a volume half that of the inside of a school bus. In total, the Soviets launched seven successful space stations (with 38 crewed missions) in a span of 11 years. Over this time, the Soviets gained valuable space station-related experience that the U.S. space program lacked. Building on past experiences, during the 1980s, the Soviets develop the Mir, a much larger space station project.

Like Salyut, Skylab (the first American space station) did not employ artificial gravity. In spite of preventive medicine, all American crews combatted nausea the first few days in orbit. However, they eventually assimilated to the weightless environment. Skylab crews conducted many scientific experiments, but their most valuable experiment gauged the effects of weightlessness on the human body. They found that minimizing muscular deterioration by instituting rigorous exercise routines was key to the success of extended manned space missions. After Skylab fell back to Earth in 1979, the American space station program stalled for five years.

In 1984, President Ronald Reagan challenged the National Aeronautics and Space Administration (NASA) to develop a permanently manned space station. Reagan also encouraged NASA to invite other nations to participate in the project. NASA spearheaded the various design initiatives of what became known as Project Freedom. By 1985, the adopted design called for the creation of a central complex (nicknamed the "Power Tower" due to its resemblance to that structure). Trusses also secured the space

station's solar arrays (a group of solar cells designed to capture energy from the sun). The European Space Agency (ESA) agreed to contribute a laboratory module. The Canadian Space Agency (CSA) pledged a mobile robotic system to do work outside the station. The Japan Aerospace Exploration Agency (JAXA), known at that time as the National Space Development Agency, agreed to supply a laboratory module and a cargo module.

As cooperative plans for the "International" space station grew in 1986, the U.S. space shuttle *Challenger* exploded seconds after liftoff. All seven crew members died. The televised *Challenger* disaster had a major influence on Project Freedom. Safety concerns were high, and they led to fewer U.S. shuttle launches and fewer construction-related space walks. In addition, a "lifeboat" was installed to allow crews to quickly evacuate the station in case of possible life-threatening emergencies. These changes increased the time it took to build the station, increased the cost of the project, and ultimately forced a reduction in the size of the station.

The cooperative agreements with other nations required each nation to pay for its own contributions. In the agreement, the United States had assumed the largest share of the cost. During a span of five years, time delays, design changes, and other unforeseen circumstances drove the U.S. portion of the bill from \$8 billion to \$30 billion. American taxpayers and the U.S. Congress began to grow weary of the mounting expense. Fortunately for the project, after the end of the Cold War (1989) and the collapse of the Soviet Union in the early 1990s, President Bill Clinton announced that Russia would also contribute to the project. It was under this new partnership that the project took on a new name: International Space Station Alpha (ISSA). The term "alpha" (first) was included in the name to specify that this was the first international effort to build a space station. However, "alpha" was later dropped from the name, and the shorter "ISS" name caught on.

The new ISS design retained about 75 percent of the Project Freedom design elements. Essentially, the ISS design included a 290-foot-long beam with four wing-like power panels at each end, which generate more energy than what would power 10 average American homes. Over time, a collection of centrally mounted modules was added. The work and living areas

of the station are equivalent to three two-bedroom homes. In 1998, the Russians added Zarya, a core module. The United States then connected two other modules (Unity in 1998 and Destiny in 2001) to the core module. The Russians added the Zvezda module, and the United States added trusses in 2000. Between 2001 and 2002, the Russians added a docking station. During that time, the United States added the Destiny laboratory as well as more trusses and a robotic arm for use outside the station.

By the early 2000s, ISS covered an area of about two football fields. The first ISS crew consisted of two Russians and one American. Later, rotating crews consisting of three to six members were sent from participating nations. In fact, the ISS has been consistently manned since the early 2000s. Construction came to a halt in 2003 after the space shuttle *Columbia* disaster, and it did not resume until 2006. Between 2007 and 2008, the United States added the Harmony node, and the ESA added a laboratory. Between 2008 and 2009, JAXA added Kibo, a Japanese experiment module. The station's trusses were completed in 2009. In 2010, the United States added two observation modules (Tranquility and Cupola), and the Russians added a research module.

The next year, Italy added the Permanent Multipurpose Module (PMM) and the Alpha Magnetic Spectrometer experiment module. In 2011, NASA retired its aging space shuttle fleet. Consequently, the United States relied on Russian Soyuz rockets to transport American astronauts to the station. Other nations, including European nations and Japan, relied on unmanned missions to deliver payloads to the station (with the ESA Automated Transfer Vehicle and the Japanese H-II Transfer Vehicle respectively). All technological equipment eventually wears out (or becomes obsolete as newer technological innovations occur) and must be replaced. The ISS is no exception; parts of it are decades old. Current mission design specs optimistically hope that the ISS will remain in operation until 2028.

Today, the ISS maintains an orbit between 173 and 286 miles above the earth and travels at an average speed of 17,227 miles an hour. ISS flight patterns are well documented, and observers on earth can occasionally catch a glimpse of the station as it zips by overhead. In addition to the cooperation between

spacefaring nations, in recent years, ISS organizers have allowed more people access to the ISS resources by making them remotely available to Earth-based commercial and scientific interests through the use of desktop control stations.

The granting of remote access to the ISS state-of-the-art technologies to Earth's commercial industries has allowed earthbound companies to work from their offices to improve various consumer products. In like manner, the possibilities for academic researchers have expanded dramatically with remote access to the same weightless environment that astronauts work in. In 2017, the official NASA Web page dedicated to providing information on the ISS contained the following motto: "Technology drives exploration." Based on the ISS's history, it could also be said that the desire to explore drives the development of new technologies. Today, the ISS is universally recognized as a world-class facility created by ongoing cooperative technological innovations and capable of producing future technological advancements.

Intraocular Contact Lens

Intraocular contact lenses differ from typical contact lenses in that they are implanted into the eye rather than being attached to the outside. Used for treating cataracts and myopia, these lenses can auto-regulate within the eye, allowing it to focus at different ranges—distance, intermediate, near, and very near. The small, flexible plastic lens is fitted with plastic

side struts that hold it in place within the capsular bag inside the eye once inserted.

Though insertion of the lens by an ocular surgeon involves only a very small incision, thus avoiding the need for stitches, there are some risks associated with such surgery, including infection, lens rotation, inflammation, and the existence of halos around lights seen at nighttime, usually while driving.

The first such lenses were implanted in 1949, but the procedure did not see common use until the late 1990s. The World Health Organization found the number of such surgeries for treatment of cataracts equaled nearly 20 million annually worldwide by 2010.

iPod

The iPod is a portable, pocket-sized computer that stores music digitally. Designed and marketed by Apple Inc., the first iteration of the iPod was released on October 23, 2001, about eight months after iTunes was introduced as an interface for purchasing digital music files or subscribing to podcasts. Designed as interdependent products, the iPod and iTunes were created to complement each other. The iPod is an MP3 player, while iTunes provided the sales of music in MP3 format. Apple cofounder Steve Jobs had a team create the company's own digital music player designed to be portable and not too big or too small. Among the 30 people chosen for this project were Tony Fadell and Ben Knauss.

Knauss went over the design flaws of previous player designs and catalogued their glitches while Fadell had the idea of attaching a sale service to the device. The aesthetic design of the iPod was inspired by the circular interface of the 1958 Braun T3

Transistor Radio. In October 2001, Jobs announced that the iPod would be compatible only with Mac computers and that it had 5 gigabytes of space, which could hold approximately 1,000 songs. The software for the iPod was not all completed in-house but in cooperation with another provider.

In July 2002, after requests from the public, Apple finally made the iPod available to Windows users. The third generation of the iPod came in April 2003 with hardware revisions, along with a new dock and another USB 2.0 port to make it easier for PC users to use. The iTunes music store was announced in the summer of 2003. The sale of MP3 files through iTunes eliminated the need for CDs, and it sped up the process of acquiring new music.

Although the introduction of the music store boosted sales of iPods, its battery power and memory size issues prompted customers to ask for a new iPod. The iPod mini was introduced with a 4 GB capacity, and it came in several colors. It was priced at \$249, much less compared to previous iPods. This was because the iPod mini cost about \$70 to make. By the time its fourth generation came along, the iPod had become such a hit that other companies tried to capitalize on the market with their own music players.

By September 2005, the iPod nano was introduced. Designed to mimic the look of hard-drive-based players, it was extremely small. It was available in 2 GB or 4 GB models and came in either black or white. The fifth-generation iPod was announced mere weeks after the nano came out, and it had a whopping 30 GB or 60 GB of space. It could also play videos. The later version had 80 GB of space and a longer battery life.

Apple introduced the iPod shuffle, a small version as small as a binder clip, containing 1 GB of space. The many iterations of the iPod finally led to one of the first smartphones. In January 2007, Jobs announced the iPhone. This device could make phone calls, send texts, surf the Web, and play music, which made the iPod obsolete. An iPhone could also download apps that did all kinds of other things, making it a revolutionary device that put the power of a computer in the palm of one's hand.

Java

Java is a programming language originally released in 1995 by computer scientist James Gosling. It is known as an “object-oriented language.” Such languages easily translate human requests into a form that a computer can understand. Java is seen as one of the most influential computer languages today because it can be easily learned and because it is so effective.

The development of Java began in June 1991 at Sun Microsystems with Gosling and a small team of programmers. One aim of Java was to run programs without the need of a compiler. The compiler is a major function in programming languages that converts code written by programmers into a form that a computer can understand. By removing the need for compilers, Java could theoretically be more applicable to widespread use.

Gosling wanted to make his language as simple and user-friendly as possible. He conducted a mini-experiment where he asked programmers if they knew the underlying workings of certain functions in the C computer language. He found that they did not, so he was inspired to create a simpler language.

To rapidly increase the community of Java programmers, Gosling made the syntax of his language very similar to that of C++; both languages are considered object-oriented. Java also manages its own memory; as a result, it is more user-friendly because there is no worry about memory leaks. However, this prevents the manipulation of some data in all the ways a programmer may desire to. As such, Java is not as

dynamic as C++ when it comes to data management. Despite the differences between these languages, Java is especially easy for programmers familiar with C++ to learn. Gosling stated that it would be more difficult for someone fluent in a programming language other than C++ to learn the syntax of Java.

Java could not meet all of its team’s ideals without making a few compromises. Particular concerns arose about Java’s resource management. Unlike C++, it does not address all fields and may not free all unused resources. This could cause the program to slow dramatically and not function at full capacity. So, Java trades a powerful tool and flexibility for user convenience and simplicity. In addition, the garbage collector implemented in Java is not consistent in performance and may result in positive, negative, or no effects after execution. Of course, no programming language is perfect, and Java is constantly updated to fix deficiencies.

Over time, Java has evolved from being a developer tool to Web tools for running programs on one’s system in embedded applications on the Web. Java has a component called “applets” that allow the user to run applications in a Web browser that supports the Java platform. This is another feature that makes Java a versatile language in its class. Further, a component known as the “servlet” allows the fulfillment of requests by the user to a Web server. This gives a software developer the freedom to create and add substance to the Web.

There are many programming languages available, but Java makes its mark as one of the best-written object-oriented programming languages. Its development team continues to improve the language by fixing bugs and adding useful features. By listening to programmers’ criticism, Java has been able to adapt itself into a very useful language for them. James Gosling has succeeded in his goal of creating a programming language that improves task efficiency, from running programs on our computers, phones, and the Internet to providing security on various networks. Java has become essential in our everyday lives.

Primary Document: Interview with James Gosling, the Creator of Java (2001)

In this interview with James Gosling, the creator of the Java programming language, he describes the philosophy of simplicity that inspired it. He wanted the interface to be as user-friendly as possible and for more people to be able to comprehend the language's functions.

A Conversation with James Gosling The inventor of Java discusses the current state of software

By Bill Venners

JavaWorld Jun 4, 2001 1:00 AM PT

Bill Venners: What have you been up to this past year?

James Gosling: Doing a lot less traveling. I'm not really going around preaching the gospel anymore. Folks are pretty converted these days. I hardly give talks at all now. I've almost exclusively switched over to doing long Q&A sessions where I get up on a stage and either people ask me questions directly, or I pull questions out of a fishbowl. For the last year I've been working at Sun Labs and ignoring all the usual corporate “goo” that comes with working at a company.

I've mostly been working on developer tools. I took a little hacking vacation earlier this year to do a relatively sophisticated Web server. It's just a pile of JavaServer Pages that manage the labs and the corporate document archive. And that has mushroomed features like mad. But my real job has been developing tools. In particular, I'm interested in tools for people who have to write code.

Most developer tools try to shield you from actually writing code in constructing the GUI bits or the database bits. Yet when you do write code you usually get glass teletypes where high tech is keyword coloring. Really high tech gives you a bit of help as you're typing in names, but that's where it ends.

So my work lately has centered on refactoring ideas, where you view a program as an algebraic

structure, and you start doing essentially algebraic transformations on the program. That's been a lot of fun.

Venners: You mean algebraic transformations in the context of refactoring your program?

Gosling: Yeah. One thing my tool will do right now is let you rename a class. Renaming a class at one level is really easy; you just change the name. But how do you change all the references to that class and all the imports? And what about renaming when it includes moving a class from one package to another? I did all this stuff to rederive all the import lists in order to deal with the various naming issues. But it's going even further. This is prototype number three, or maybe number four.

Venners: Will this tool be seen outside of Sun? More than 500 programming languages are available to create our digital world.

Gosling: Yes. If it gets to the state where it looks like it might have even a vague chance of being interesting. My hope is to throw it over the wall some day.

The complexity challenge

Venners: In several recent interviews, you claim that the main challenge for programmers is complexity. Can you elaborate?

Gosling: In some sense, that's what this tool I am building is all about. How do you write a complex application? How do you deal with an application that's a million lines long? How do you even come close to understanding it? How do you make a change to a system like that? How can you cope with it?

Another axis of complexity exists as you lay the application out on a network. One of the things that Java is good at is giving you this homogeneous view of a reality that's usually very heterogeneous. One of the things going gangbusters recently is the cell

phone business. The last time I heard a number, it was like 60,000 Java cell phones were being shipped every day. The numbers have become staggering. And that's not the highest volume Java platform. The highest is actually smart cards, and that's a really big number, although I don't know the exact number.

People building these applications that span the network from edge to center to edge, where you have part of the application in whatever the edge device is—whether it's desktop or cell phone or PDA—some bits and pieces in the infrastructure, and some bits and pieces in the back ends and the databases. One person can work from end to end, but how do you manage the complexity of that?

We don't have really good ways to deal with that issue. We just barely have tools that let us look at what one system is doing and map that across an end-to-end architecture. There are people who have these embedded debuggers for dealing with things like J2ME devices. How do you debug code that's inside your Oracle database? How do you look at the whole thing in totality? That's the hard and interesting problem. The systems being built get more and more complicated every day.

I spent a lot of time a couple of years ago on the whole real-time effort. The motivation for that came entirely from the real-time community. The main issue was that programmers are not writing a few thousand lines of assembly code anymore. These systems are getting really huge. And Java has proven to be pretty successful in building large reliable systems.

Venners: I'm glad I asked that question because I thought you might have been talking more about the complexity of large, monolithic programs.

Gosling: Yes, even isolated things. Some of these isolated applications that sit on one machine are a million lines of code. How do you deal with that? Most people have no way to wrap their head around it. There are all kinds of tools available, from organizational tool you get from object-oriented methodology, to some of the tools that are based on that, like UML modeling.

But of course the more tools you build to cope with such complexity, the more complex things become. We always strain at the limits of our ability to comprehend the artifacts we construct—and that's true for software and for skyscrapers.

Venners: Increasing complexity is also being driven by hardware that's getting cheaper and more powerful.

Gosling: Absolutely. One of my favorite lines is that computers are driven by Moore's Law, which is an exponential process, and human beings are driven by Darwinism.

Venners: And that's a linear process or what?

Gosling: One way to look at it is as a Monte Carlo process. In Monte Carlo algorithms, the precision of the result doubles as you double the amount of time. So you're getting better on a square root kind of a curve, whereas computers are going on a two-to-the-N kind of curve. Their curvature points in opposite directions. How do people with skulls of a limited size deal with that?

The role of simplicity

Venners: The opposite of complexity is simplicity. I have often heard you describe your philosophy when designing Java in the early days: you didn't put something in Java unless five people screamed at you and demanded it. In one interview, you told this really good story about moving to a new apartment and something about keeping things in boxes.

Gosling: That's actually a general principle for life that works really well. When you move to a new apartment, don't unpack. Just sort of move in, and as you need things, pull them out of the boxes. After you've been in the apartment for a couple of months, take the boxes—don't even open them—and just leave what's in there and throw them out.

Venners: The "don't even open them" part is important because it's very hard to throw things away once you know what they are.

Gosling: Right, because if you open them, you say, "oh, I can't part with that."

Venners: So would you say that simplicity is a general philosophy programmers should always have when designing programs?

Gosling: I think in any kind of design, you must drive for simplicity all the time. If you don't, complexity will nail you. Dealing with complexity is hard enough.

In programming language design, one of the standard problems is that the language grows so complex that nobody can understand it. One of the little experiments I tried was asking people about the

rules for unsigned arithmetic in C. It turns out nobody understands how unsigned arithmetic in C works. There are a few obvious things that people understand, but many people don't understand it.

So one of the most important criteria for judging a design for me is the manual. Is the manual out of control, or is it reasonably concise? You can write a

pretty decent Java manual in less than 100 pages. The current Java language spec is pretty thick, but that's because it's probably the most detailed language spec ever written. It goes through all of the details. I couldn't write the Java language spec.

Jemison, Mae (1956–)

In 1992, physician and astronaut Mae Jemison became the first African American woman in space when she worked for the National Aeronautics and Space Administration (NASA) as mission specialist on the space shuttle *Endeavor*.

Born in 1956 to Dorothy Green Jemison, an English and math teacher, and Charlie Jemison, a charity supervisor and carpenter, Jemison had childhood aspirations to travel into space. When she was three years

old, the family moved from Alabama to Chicago. Jemison was inspired by Martin Luther King Jr. to be brave and to cross racial and gender barriers. She also enjoyed watching *Star Trek*, a television show about space travel. The show featured Lt. Uhura, a female communications officer of African descent who appeared in the first episode in 1966 and most episodes afterward.

Jemison graduated from high school in 1973 and was accepted by Stanford University when she was 16 years old. She graduated four years later, a rare black female chemical engineering major. In 1981, Jemison earned her medical degree at Cornell University. She also continued to dance, building on an interest she had first developed in high school.

Once Jemison's medical training finished in 1983, she joined the Peace Corps medical staff and served in West Africa, primarily in Sierra Leone and Liberia. While in Africa, she also worked with the Centers for Disease Control (CDC) on vaccine research. In 1983, the year Jemison went to Africa, Sally Ride became the first American woman astronaut in space. In response, Jemison applied to NASA's space program but was not accepted. Four years later, NASA invited her to reapply. She joined the first astronaut training class after the *Challenger* shuttle explosion in 1986, which had killed all seven of its crew members. In the wake of the disaster, shuttle missions were canceled. In 1988, space shuttle *Discovery* launched, reopening NASA's manned space exploration program.

Jemison's first job at NASA was at the Kennedy Space Center, where she worked in the Shuttle Avionics Integration Laboratory. On September 12, 1992, Jemison was aboard the *Endeavour* as it launched into space as STS-47, Spacelab-J. For eight days, she

Engineer and physician Mae Jemison was the first African American woman in space. She orbited the Earth on the Space Shuttle *Endeavour* in 1992. (NASA)

orbited the earth on the NASA's 50th space shuttle mission. The mission contained a space lab module where astronauts conducted experiments on the effects of microgravity on both materials and living systems. The mission also included the first married astronauts, Jan Davis and Mark C. Lee. STS-47 was also notable for being a mission in cooperation with Japan. As homage to her love of dance, Jemison took a poster for the Alvin Ailey American Dance Theater, a modern dance company based in New York, into space. She also took a picture of Bessie Coleman, the United States' first black woman pilot.

In 1993, Jemison resigned from NASA to better explore the connections between science and the humanities. She founded the Jemison Group to research and market usable, everyday technologies. That same year, she also established the Dorothy Jemison Foundation for excellence. Named for her mother, the not-for-profit organization funds and develops educational programs, teaching methods, and curricula to improve critical thinking and learning by doing. In 1994, the foundation launched The Earth We Share (TEWS), an international science camp program that encourages young people to consider contemporary scientific and environmental issues.

In 1993, Jemison also made her first appearance on television, in a *Star Trek: The Next Generation* episode. She was the first real astronaut to ever appear on *Star Trek*. She has also hosted the Discovery Channel's *World of Wonder*, and in 2006, she appeared in PBS's *African American Lives*.

In 1995, Jemison became a professor in environmental studies at Cornell University and three years later joined First Lady Michelle Obama at a forum for girls in the Washington, D.C., school district. In 1996, Jemison said she had been a victim of police brutality during a routine traffic stop. In both her complaint and in interviews, Jemison said an officer both physically and verbally abused her.

In 2012, the Dorothy Jemison foundation won the bid for the 100 Year Starship Project to create a century-long plan to fund and carry out space travel.

Joystick/Flight Simulator

The joystick is the principal controlling device in a cockpit, and it revolutionized the flight simulator industry. All aircraft now have some form of joystick for operation.

The earliest forms of flight simulators were used in 1910, just on the cusp of World War I. These simulators did not rely on wind; they were manually controlled by two people who adjust their altitude levels using pedals while the pilot compensated accordingly. There are multiple reports of the first joystick patents, varying from a U.S. patent in 1926 to a German patent relating to bombers in 1944. By 1960, joysticks were ubiquitous in all flight simulators, which were controlled using radio frequencies.

The joystick is also fundamental in the video game industry, allowing users to easily control characters. Its implementation led to the rise of arcade-style games such as *Pac-Man* and *Dig Dug*. The joystick is now incorporated into most video games today.

Kurzweil, Ray (1948–)

Ray Kurzweil is an American author known for many nonfiction publications, revolutionary inventions, and his place in the National Inventors Hall of Fame. His ideas in computer science, the future of technology, and insight on sentience have solidified his name in history as a “future-proof” inventor. His most famous invention is the CCD flatbed scanner.

Kurzweil was born on February 12, 1948, in New York City, and he desired to be an inventor very early in his life. According to several interviews, he built his own robotic game when he was 8 years old and published a paper detailing sensory perception at 14. After pursuing his love for computers in high school, his first company; Kurzweil Computer Products Inc., was founded in 1974. This company helped Kurzweil invent revolutionary machines. Some examples are the aforementioned CCD scanner, a text-to-speech synthesizer, and the Kurzweil reading machine. After the company had much success, it was sold and was eventually owned by Xerox, while Kurzweil quickly moved toward his next project: music.

His next company was founded in 1982 and was known as Kurzweil Music Systems. There, he invented the Kurzweil K250, a machine that synthesized music—another first. After he sold that company in 1990, Kurzweil took to writing and published his first book, *The Age of Spiritual Machines*. Translated into nine different languages, it was a *New York Times* best seller and successfully predicted the future of artificial intelligence for the next decade. His additional publications include *The Singularity Is Near*, *How to Create a Mind: The Secret of Human Thought Revealed*, and *The Age of Intelligent Machines*.

His insight was soon recognized, and he was awarded the National Medal of Technology in 1999 for his inventions from the preceding decade. In 2002, Google offered Kurzweil a position, allowing him to expand on his innovations for the future. He was involved in the creation of the Google Assistant, and using Kurzweil's speech recognition machines, Google successfully launched Google Now. It is continuously improving the software's realism and accuracy.

Kurzweil has been the director of engineering at Google and runs his own Web site that automatically updates with any breakthroughs in science and technology. It averages over 3 million new readers every year. Kurzweil plans to donate his body to science and is researching methods to extend or revive life.

Linux

Linux (generally pronounced LIH-nuhks) is an operating system designed to provide personal computer users with a free or very low-cost operating system comparable to traditional and usually more expensive Unix systems.

Though Swedish computer science student Linus Torvalds developed Linux in 1991, the system has its roots in a number of American computer science endeavors. In 1969, Ken Thompson and Dennis Richie developed the Unix operating system (OS) while working at AT&T's Bell Laboratories. Not long afterward, they redeveloped Unix to make it more portable. They called this OS "C." This version of Unix became popular with university and business computing systems. In 1983, Richard Stallman, working at the Massachusetts Institute of Technology (MIT), announced the GNU project, which was aimed at using mass collaboration to create free software programs. GNU developed HURD, a multiserver OS, but the software never attracted enough collaborators to become more than an incomplete idea. Nonetheless, the impetus for free operating software (and other kinds of software) had been launched.

In 1991, Linus Torvalds developed the Linux kernel as a Unix-like OS for use in personal computers and other systems. Torvalds wanted to call his software "Freax," a combination of the words "free" and "freak," with the *x* as an homage to Unix. One of the volunteer administrators at Helsinki University thought Freax was a bad name and uploaded it as "Linux," a combination of "Linus" and "Unix." Torvalds thought the name too egotistical, but he eventually agreed to its use. In 1992, Torvalds suggested uploading the Linux kernel under GNU, making it free. He later described this decision as the best he'd ever made. Once Linux was uploaded to GNU,

thousands of programmers worked on the software to expand and improve its operation.

In 1992, computer scientist Andrew Tanenbaum declared Linux obsolete. Tanenbaum said the kernel was too big and not portable enough for modern processors. Most important, he said that because Linux was open source and the product of worldwide collaboration, its largest weakness was that it had no single person or corporation in control. Tanenbaum declared that Linux would be replaced by HURD in the very near future. This prediction proved incorrect, but programmers saw the criticism as a call to modernize Linux.

Over the years, Linux's main OS competition has come from Microsoft, a company whose software programs are most assuredly not free. Commercial software companies see free software as a threat to profit making, though the success of Microsoft would suggest otherwise. Microsoft funded a number of studies to discredit Linux, but as soon as these studies were published, programmers refuted them with studies and papers of their own. In 2009, GNU received 22,000 lines of code from Microsoft, effectively ending the software feud. However altruistic the move to donate code to an open-source, free software platform might have been considered, it appears that Microsoft had been forced to donate the code when a Linux contributor discovered that the company had incorporated GNU software into its own products.

In 2000, the Open Source Development Labs (OSDL), a not-for-profit organization, was established in San Francisco, dedicated to optimizing Linux and developing other free software applications. Seven years later, OSDL merged with the Free Standards Group to establish the Linux Foundation. Linus Torvalds is a foundation fellow. Today, Android tablets, smart watches, and smartphones use Linux-based OSs. While the vast majority of personal computers do not use Linux, 500 of the world's supercomputers do.

Maker Faire

Maker Faire is described by Maker Media as “the Greatest Show (and Tell) on Earth.” The fair consists of numerous do-it-yourself (DIY) fans who get together several times a year, every year, to showcase their creations to visitors. DIY projects are self-explanatory—most of their materials and tools are often easy to buy locally or online. Since most DIY projects are built at home or privately, very few of them ever become well known or come to the attention of people far away. Maker Faire provides a solution by allowing inventors, hobbyists, crafters, and clubs to exhibit their creations and educate visitors.

“Makers” are part of “the Maker Movement,” a movement that encourages advancements in DIY creation. It includes technological achievements such as in robotics as well as in traditional achievements such as woodworking or sewing. For example, the Luck Dragon project looks like something from the movie *The Neverending Story* and moves around on wheels. At the Faire, arts such as photography, music, and fashion are also welcome. Grow Bucket Life was a kit available for sale at the 2017 San Mateo Maker Faire. It was created by a San Franciscan named Ruth Grace to allow customers to grow plants requiring lots of light in a bucket indoors. The event attracts people of all ages and different backgrounds, so there is a vast variety of visitors and exhibitors alike.

There are two types of Maker Faire: Flagship and Mini. Flagship Maker Faires are large events, with the largest yet held in San Mateo, California, in May 19, 2017, with an attendance of over 150,000 visitors and over 1,300 exhibitors. These Faires are directly sponsored by Maker Media. The best-known Flagships occur in San Mateo and New York, with the San Mateo Maker Faire known as Maker Faire Bay Area and the New York Maker Faire known as the “World Maker Faire.”

Mini Maker Faires, on the other hand, are smaller scale and are run by independent organizers in the

community, working with Maker Media for the fair to run properly. Many of them also occur outside of the United States, reaching as far as Australia, China, and Europe. A third, lesser known type of Maker Faire is a School Maker Faire; a school hosts it, and most of the Makers are students or teachers. These fairs bring attention from the younger generations to the Maker Movement and encourage students from kindergarten to the high school level to try new things and learn more about technology. Knowing that their peers can do something they might have thought was impossible shows them that they can also do it if they try.

Companion pieces to the Faires are the twice-per-month *Make: Magazine* and the DIY kits from Maker Shed. *Make: Magazine* features countless DIY projects and STEM concepts that can be implemented without high-tech tools. Maker Shed's DIY kits teach users about science and procedures for achieving an expected result while acting as a fun learning tool for children and adults. The magazine and the kits were created to teach and were the initial reasons for the creation of the Faire.

The Faire all began with Dale Dougherty, the founder of Maker Media, Maker Faire's parent company. He and Sherry Huss, the vice president of Maker Media, started "the Maker Movement" with Maker Media's creation. After opening two offices in San Francisco and Sebastopol, California, they began *Make: Magazine* to communicate their message to the public. *Make: Magazine* started in January 2005 to publicize DIY projects to its subscribers. Many of the first projects were simple and required items that were easily found at home. As the customer base increased, Maker Media decided to hold their first ever Maker Faire to celebrate the enthusiasm shown by subscribers.

The Faire took place in April 2006 at the fairgrounds of San Mateo, California. It was a huge hit as visitors enjoyed the hands-on activities and learning new skills from demonstrators. The event became annual and soon spread to the rest of the United States, beginning with Texas in 2007. The first ever Mini Maker Faire started in 2009 as a collaboration with the Newcastle Science Fest in Newcastle, United Kingdom. By 2013, Maker Faire was international, with about 100 fairs. Seven were Flagship Maker Faires, and 93 were Mini Maker Faires.

One Maker Faire was even hosted by President Obama at the White House in 2014. This proved to be an important time for the Maker Movement, as the event was called "The Day of Making." That day, several Makers were chosen to share how their lives had been affected by becoming Makers. In 2015, the 10-year anniversary of the Faires, Maker Faire Bay Area was celebrated in San Mateo, with Google acting as a sponsor for the "Learn to Solder" and Goldsmith projects. Over a thousand people visited, with many coming from outside of California. San Mateo, San Francisco, and Oakland even declared that week "Maker Week." It was also the sixth anniversary of the Maker Faire of New York City, and that week was also declared "Maker Week." That same year, 150 fairs occurred globally.

In 2016, Intel and Barnes & Noble joined the list of sponsors for Maker Faire Bay Area along with several others, such as LinkedIn, Roboterra, and Thinglogix acting as sponsors for school attendees. The White House Maker Faire also continued, except that it became a Flagship known as the "National Maker Faire." In 2017, the innovation increased when food became even more integrated with Maker Faire Bay Area with a new section consisting of 15 exhibitors called "Future Food Area."

With the fast rate at which technology is advancing, it is important to keep up. New things are being created or discovered every day, and it can be easy to fall behind. Maker Faire is one way to remain up to date and on track along the road to discovery. The Makers that appear during the Faire know the whats and whys behind their creations and can teach them to visitors. Exhibitors and visitors alike come from all over, some even traveling internationally, so the methods used and exchanged can be rather unusual. There have always been science fairs, but they tend to be competitions that are about who created the best project. The Maker Faire contains ordinary people with extraordinary everyday discoveries.

Since socializing is an important part of human nature, the Maker Faire can play an important role in a young person's life. It is not hard to find someone with a similar mind-set or set of ideals at Maker Faire. It is also easy to find at least one thing that interests or at least amuses you there. From the 3-D drawing pen to

the handmade dolls, there is something for anyone with a hobby. It is also the perfect place for discovering a hobby, since many Makers are hobbyists in their own right. The large variety of demonstrations and products available allows people to try new things and discover something worth investing time and money into. Most Flagship Maker Faires are annually but occur at different times of the year, so they are convenient for many attendees.

March for Science

The March for Science, originally conceived as the Scientists’ March on Washington, took place in over 600 cities in April 2017.

Interest in a pro-science protest stemmed from the 2016 election of Donald Trump. By early 2017, it was clear that Trump’s political appointments to science-related public organizations like the U.S. Environmental Protection Agency (EPA) and the Department of Energy (DOE) would be antiscience, anti-climate change, anti-environment, and against fact-based evidence. March organizers pointed to Trump’s claim that climate change was a hoax perpetrated upon the United

States by China and an administration science advisor’s claim that belief in climate change was cult-like.

Inspired by the January 2017 Women’s March, which had between 3 and 5 million participants worldwide, Science March organizers planned a similar protest. A march announcement that beloved science communicator Bill Nye would lead it only increased the event’s public support.

Marchers, when polled, said their aims for the march were to encourage public officials to make policy decisions based on scientific facts, to oppose political attacks on science and scientists, to protest cuts to science funding, and to promote scientific literacy among Americans.

Mars Rover Series

The Mars rover series includes all rover missions to the planet Mars. A rover is an automated motor vehicle that propels itself across the surface of a planet after landing. Rovers are primarily used to research and characterize the surface of a planet to increase scientific knowledge. Most recently, rover missions to Mars have examined the rocks and soil on the planet to learn about possible past water movement and possible life activity. The Mars rover missions have been led by the U.S. National Aeronautics and Space Administration (NASA), partnered with the Jet Propulsions Laboratory (JPL). The rovers are supplied with instruments to identify and study samples from Mars. For example, the most recent rover, *Opportunity*, contains a miniature thermal emission spectrometer to provide temperature readings of the Mars atmosphere. It also contains an alpha particle x-ray and imager for close-up analysis.

The first space missions to learn more about Mars were planned in the late 1950s. These were mostly

NASA engineers Christopher Voorhees and Brian Harrington test the Mars Exploration Rover B, or *Opportunity*, for mobility. There have been four successful Mars rovers. (NASA/Jet Propulsion Laboratory)

orbiters and landers that never roamed the surface of the planet. However, the early missions did provide an extensive amount of information regarding its atmosphere and surface composition. These early missions directly influenced the success of future rover missions.

There have been four successful rover landings for the United States since NASA created the Mars Exploration Program in 1992. The first successful rover, *Sojourner*, landed on July 4, 1997; however NASA lost communication with it shortly afterward. The second mission, with the rover *Spirit*, landed in 2004; it roamed a total of 4.8 miles, supplying scientists with much information about the planet's rock and soil composition. *Spirit* remained active until its deactivation in 2010 due to being stuck in a sand dune. The third mission, with the still-active Mars rover named *Opportunity*, landed in 2004. The JPL managed the now-defunct *Sojourner*, while NASA continues to operate *Opportunity*.

After *Spirit* found evidence of past water activity, *Opportunity* has tried to gather as many samples as possible to learn more about it. The most recent rover, *Curiosity*, landed on Mars in 2011 and is still operational. JPL and NASA updated this rover with more instruments for examining and analyzing samples. It also has been upgraded to travel faster and farther, with additional heat shields to make it more durable during its mission on Mars. The primary goals of *Spirit* and *Opportunity* are to discover the history of water on Mars and then to determine whether life ever arose on it. The most recent information about past water activity suggests that there is no life currently viable on the surface of the planet.

These last two rover missions have made a lasting impact on space exploration. The evidence of past water activity created a demand for more exploration. There is still much more that NASA and JPL have in store for these rover missions. A new Mars rover is set

to launch in 2020 if there are no difficulties with building it. This mission intends to investigate certain environments on the planet to determine if there is any history of past life. It will have a similar design to *Curiosity* but will include more instruments like drills and sensors that will extract samples and quickly scan for carbon. JPL will be in charge of carrying out the mission if it receives enough funding. Even when the rovers are unable to move, researchers have found ways to continue using them. Regardless of the success of their primary missions, old rovers can still transmit data and act as stationary cameras.

MIDI (Musical Instrument Digital Interface)

Musical Instrument Digital Interface (MIDI) is a way to connect devices that make and control sounds. It connects synthesizers, samplers, and computers using MIDI messages so that they can communicate with each other. This capability enables a keyboard to trigger sounds on another synthesizer, making it possible to record music in a form that grants easy note editing, flexible orchestration, and song arrangement.

MIDI first appeared in 1982 as a compromise among manufacturers and developers of electronic musical instruments to include a common set of hardware connectors and digital codes in their instrument design. In 1983, the MIDI 1.0 Specification was released by the International MIDI Association while music-oriented corporations such as Roland, Yamaha,

Korg, Kawai, and Sequential Circuits all came out with MIDI-capable instruments that year. The idea for MIDI actually dates back to 1978, when Dave Smith, an engineer and synthesizer designer, put out one of the earliest musical instruments to include a microprocessor, the Prophet 5.

The Prophet 5's efficiency was its key feature, as it allowed a sufficient amount of information to be transmitted using only a small amount of data, which ensured that the reproduction of musical timing was acceptably accurate compared to early 1980s digital transmission methods, which had limitations. Although MIDI was popular, it did have some criticisms related to timing issues that resulted in apparent sloppiness in recording and playback. An even more noticeable flaw was the delay between triggering a function via MIDI and the function being carried out, as when sound was reproduced.

It has been over 30 years since the development of MIDI and its revolutionizing of the world of music recording. It allowed synthesizers and drum machines to be connected to computers, an important feature in creating some styles of music. For example, if middle C is struck on a keyboard hooked up to a laptop, MIDI turns all of the information about that note, such as its timbre, length, and volume, into code that can then be changed or manipulated by the computer. In addition, that C can become a D or be dragged out to twice its length. The possibilities are nearly endless. Keyboards aren't the only things that can plug into MIDI. Electric guitars, violins, basses, and more can be played and their sound manipulated. MIDI isn't just used for music; it's also used to control lights and animatronics.

Moore, Ann (1934–)

An American nurse, Ann Moore, is credited as the inventor of the Snuggly and Weego child carriers. As a Peace Corps nurse during the 1960s in Togo, West Africa, she noticed that mothers carried their babies in fabric slings. The babies were calm and secure because they were close to their mothers. When Moore returned home and gave birth to her daughter Mandela, she wanted to carry her in the same way. Moore first tried to secure Mandela on her back in the manner she had observed in Africa, but the baby kept slipping. Using a basic backpack and then adapting it to their needs, Moore and her mother designed a carrier that was similar to those used by women in Togo. In this way, the two devised the original soft baby carrier, the Snuggly, as well as other types of specialized carrying cases. Evenflo now makes Moore's child carriers, selling 327,000 units between July 1996 and May 1999. Today, Moore works in the innovation of carrying cases for medical and high-tech instruments.

MP3

"MP3" is the abbreviation of "MPEG-1" or "MPEG-2 Audio Layer III," which is an audio coding format for digital audio. It allows a user to make a duplicate of an original audio file with no appreciable loss of sound quality. MP3 technologies can also facilitate storage of digital files and have become common methods of compressing digital information for transfer and playback on audio players.

The original MP3 technologies were confined to audio engineers who used the technology largely for voice compression. Only later was MP3 technology used for music compression, which allowed for the

development of the iPod and other digital music-streaming technologies. But it is MP3 technology that is largely responsible for the shakeup in the traditional recorded music industry, the proliferation of portable music players and mobile phone music services now available, and the streaming of media content.

Many engineers credit a German graduate student, Karlheinz Brandenburg, as the source of one of the pivotal moments in digital music compression that began in the early 1980s at the University of Erlangen-Nuremberg. One of Brandenburg's professors urged him to work on the problem of how to transmit music over an Integrated Services Digital Network (ISDN) phone line, and Brandenburg began working on his PhD dissertation in audio compression. He realized that transmitting media content over the ISDN line was not just a technical matter; it also depended on how people perceived the quality of music. He used a Suzanne Vega song, "Tom's Diner," as his test product, and he attempted a number of methods to compress the signal without losing audio quality.

Among the major companies that were also experimenting with MP3 technology at the time were Alcatel-Lucent, Microsoft, Bell Labs, and others, but their experiments were not limited to audio alone. Instead, they were focusing on how to compress video and audio for use over telephone lines. But Brandenburg's contributions understood best the need for a high-quality system that replicated original sound quality, and his developments translated to the use of the Internet for distribution.

In 1997, an entrepreneur by the name of Michael Robertson created MP3.com, a Web site that could be used to find free music on the Internet. The company bought 45,000 CDs and loaded them into an internal server for unlimited use by customers; it was quickly sued by the Recording Industry Association of America (RIAA) for copyright infringement and forced to shut down.

Around the same time, Shawn Fanning had the idea in his Northeastern University dorm room that Internet Relay Chat (IRC) protocol could be used as a model for using MP3 technology to share music. He planned to set up a central server that allowed users to connect and share the digital music they had stored on their own computer hard drives. By 1999, he was

working on developing code that allowed peer-to-peer file sharing for the purpose of sharing music, and he called his nascent company Napster. Though Napster was challenged by the RIAA and forced to shut down, so much attention had been given to the downloading and distribution of music that the recorded music industry was forced to radically change its business model.

MP3 technology allowed many companies to compete in the emerging digital music market. Apple used MP3 to develop its iPod media player and the iTunes download service. Other companies also used MP3 to develop their own digital music players, such as Nullsoft's audio player Winamp, developed in 1977, and the first solid-state digital audio player, MPMan, developed by SaeHan Information Systems in Seoul, South Korea, in 1998.

Today, MP3 technology is used for a wide variety of audio devices. Smartphones use it, computers use it, and audio systems in cars use it. Recorded audiobooks on CD are often created with the use of MP3 files, and practically any audio signal over the Internet can use the technology to transfer audio. Over time, the technology has become so refined that it can compress a digital audio signal into a package nearly 1,000 percent smaller than the original, noncompressed sound signal, and it can do so without any loss of sound quality. MP3 technology is largely responsible for the development of streaming services, both audio and video.

Negroponte, Nicholas (1943–)

Nicholas Negroponte, an architect and computer scientist, is the founder of One Laptop per Child and cofounder of programs such as the Media Lab at the Massachusetts Institute of Technology (MIT). He is

the author of *Being Digital* and *Unleashing the Killer App: Digital Strategies for Market Dominance*.

Negroponte was born in New York City to Greek immigrants Dimitri John Negroponte and Catherine Coumantaros. He has three brothers: John Negroponte, former U.S. deputy secretary of state; Michael Negroponte, an Emmy Award-winning director; and George Negroponte, an artist who had been named president of the Drawing Center from 2002 to 2007. Negroponte attended multiple schools in his adolescence, including Buckley School in New York, Fay School in Massachusetts, Le Rosey in Switzerland, and Choate (now Choate Rosemary Hall) in Wallingford, Connecticut. He then studied architecture at MIT, where he earned a master's degree in architecture in 1966.

Negroponte began working at MIT in 1966 and taught as a visiting scholar at other universities, including the University of California, Berkeley; Yale; and Michigan State. It was at MIT that Negroponte founded his first organization in 1967 called MIT's Architecture Machine Group. The purpose of this group was to study new approaches to human-computer interaction. He went on to cocreate the MIT Media Lab alongside Jerome B. Wiesner. The MIT Media Lab serves as a workshop for invention and innovation in the fields of technology, multimedia, science, art, and design.

In 1992, Negroponte aided in the development of *Wired* magazine, which focuses on the developing relationship between technology and culture. He has received opposition for his views from other scholars who believe that he fails to consider the consequences of new technology. It is also from his monthly column in *Wired* magazine that he compiled his work for the book *Being Digital*, which was published in 1995.

In *Being Digital*, Negroponte makes predictions about the future of society's relationship with technology. The phrase "Negroponte Switch" originated from the book and refers to his prediction of the switch from receiving and sending information using cables to doing so using airwaves. He also predicted that touch screens and voice recognition software would develop and replace the mouse and pointer in interactive technology. He has appeared to be accurate, as smartphones and tablets use these methods. He has been

labeled as a “digital optimist” for believing in the benefits of technologically advanced living. This book became a best seller and has been translated into over 20 languages.

In 2000, Negroponte resigned as the director of the Media Lab but continued to act as laboratory chairman until 2006, when he stepped down to focus his attention on the One Laptop per Child Project. Negroponte has contributed to the start-ups of over 30 companies as an angel investor and sits on boards for Motorola and Velti. In 2005, he personally founded the idea of \$100 tablets to aid in the classrooms of children in developing countries. This project has had different names. Originally called the \$100 Laptop, then The Children’s Machine and 2B, it is currently known as OLPC XO. Negroponte designed this laptop for children in developing countries to be compact and durable. It is lightweight and uses an internal SD memory in place of a hard drive. It can also be equipped with different modes to collect power such as a standard plug, human power (a hand crank), and solar power. Externally, it is dirt and moisture resistant and has a sealed, rubber membrane keyboard. The price for these laptops has since increased to \$180.

Netscape

Netscape or Netscape Navigator was the first widely used Web browser, though it lost its market share in the first so-called Browser War. Netscape was the first company to capitalize on the newly formed World Wide Web.

While working at the Advanced Research Projects Agency in 1963, a psychoacoustics expert named J. C. R. Licklider proposed the idea of a network of computers working together to solve complex problems in real time. His colleagues followed that idea to create ARPANET, the precursor of today’s Internet. Initially, only four computers made up ARPANET, connecting Stanford Research Institute; University of California, Santa Barbara; University of California Los Angeles; and the University of Utah. Incompatibilities between the ARPANET computers, however, led to the development of standardized networking protocols, such as TCP/IP. Other innovations soon followed, such as e-mail, telnet, and file transfer protocol (FTP).

As ARPANET added more computer nodes to its member institutions, it formed in-house or local area networks (LANs). One of these LANs, NSFNET, connected the major supercomputer centers and several universities in 1986. Eventually, NSFNET replaced ARPANET and became the foundation of the modern Internet. As more information flowed across the early Internet, additional protocols and applications became necessary to use it. Participating institutions and users could read electronic bulletin boards, access large databases, communicate with newsgroups, and perform sophisticated queries, but they had to do so with technically complex instructions and a command line interface.

Then, in 1990, Timothy Berners-Lee created Hypertext Markup Language (HTML), which was the basis of his World Wide Web software (later called Nexus) in order to edit and share documents with his colleagues across a computer network. This achievement caught the attention of a student named Marc Andreessen at the University of Illinois at Urbana-Champaign.

At the age of nine, Marc Andreessen had taught himself to write programs in the BASIC language on his TRS-80 computer. By high school, however, he had become bored with computers and only reluctantly chose computer science as his college major. Later, he led a team of programmers at the University of Illinois National Center for Supercomputing Applications (NCSA) to write the Mosaic browser. Mosaic was the most advanced Internet browser in 1993, when NCSA released its source code. Compatible with

several networking protocols and offering a user-friendly, point-and-click interface, Mosaic allowed nontechnical users to share a wider range of content with relative ease.

Upon graduating from college, Andreessen was contacted by James H. Clark, a cofounder and former employee of Silicon Graphics Inc. While Marc envisioned the global impact of the Internet browser, Jim realized its commercial appeal. Together, they formed a new company called Netscape. Andreessen would recruit programmers to make their new product called Netscape Navigator, while Clark put up the seed money for the venture. Some of Clark's former coworkers from SGI also joined the team of engineers at Netscape. Although loosely based on the Mosaic browser, Navigator received two key improvements. The programmers added graphics to the somewhat boring, text-based interface, and they converted it from a Unix-based application to one that worked with Microsoft Windows, an operating system that was running on at least 80 percent of personal computers at the time. Four years later, 50 million people were using the Internet. Netscape remained the technical leader in the Internet browser market through the 1990s, adding more innovations such as independently displayed graphics and text, compatibility with third-party applications, cookies, frames, and JavaScript.

Sixteen months after it was founded, Netscape became a publicly traded company. Netscape's share price was \$28 prior to its initial public offering (IPO). At the opening bell on August 9, 1995, the price rocketed up, reaching as high as \$74.75 per share. At the close of trading that day, Netscape's share price had settled to \$58.25. Lou Montulli had previously joked about his \$600 monthly salary as an engineer for Mosaic. On August 10, 1995, this ragtag group of hungry young programmers had become millionaires overnight. Their incredible success stimulated a firestorm of investing and speculating that seemed like a modern-day gold rush. Fearful of missing the opportunity to ride the Internet wave, venture capitalists poured millions into all kinds of dot-coms. No idea was too outrageous. Some of these tech start-ups, such as Amazon, Priceline, and eBay, for example, succeeded. Netscape's stock reached \$171 per share by the end of 1995.

Fifteen days after Netscape went public, Microsoft released its germinal operating system, Windows 95, without a Web browser, because it had not yet developed one. With help from a Mosaic licensing partner called Spyglass, Microsoft released its first browser, Internet Explorer, with the Windows 95 Plus! Pack. During a legal dispute with Spyglass, Microsoft revealed that it was bundling Internet Explorer with the Windows operating system. Put another way, Microsoft claimed that Internet Explorer was not a separate product from Windows—rather, it was an integrated feature of Windows. This critical point became the basis of Microsoft's defense against a lawsuit brought by the U.S. Department of Justice in 2000. In his finding of fact, Justice Thomas Penfield Jackson declared that Microsoft had abused its monopolistic power by diminishing the presence of competing products on the Windows desktop through negotiations with computer manufacturers by attempting to dissuade Netscape from developing Navigator as a platform and by excluding Navigator from important distribution channels.

Despite these findings, Microsoft continued to dominate the operating system market with Windows and gradually pushed Netscape out of the public eye while increasing the functionality of Internet Explorer. Netscape released its source code and created the Mozilla Organization to coordinate future projects. In 1999, AOL acquired the remaining Netscape stock for about \$10 billion. In the mid-1990s, Netscape's usage share was 90 percent. By 2006, it had dropped to less than 1 percent. Microsoft had won the Browser Wars.

Nye, Bill (1955–)

Known worldwide as “Bill Nye the Science Guy,” from his public television show of the same name, Bill Nye is the most famous science communicator in the United States and is known for his wacky performance style and iconic bow ties.

Born William Sanford Nye in 1955, Nye graduated from Cornell University with a degree in mechanical engineering in 1977. His first job was for Boeing, an aviation company in Seattle, Washington. In 1986, Nye quit his job so that he could devote more time to his comedy career. In 1993, Nye developed his now famous *Bill Nye the Science Guy* for a public television station in Seattle, pitching the show as a mash-up

Loved by generations of young Americans, Bill Nye is one of the nation's great public scientists. His PBS show *Bill Nye the Science Guy* and Netflix show *Bill Nye Saves the World*, along with his quirky personality and colorful bowties, have made him famous around the world. (Carrielson1/Dreamstime.com)

of *Pee-wee's Playhouse* and Mr. Wizard. The show quickly gained an audience of both children and adults and was picked up by public television stations across the country. The show's immense popularity disguised its effective science teaching with humor and fast-paced action. The show ran for 100 episodes.

In the 21st century, Nye has taken on more controversial science topics, including challenging climate change and evolution deniers and warning of the dangers of genetically modified foods. In 2017, Nye returned to video, if not television, with the Netflix show *Bill Nye Saves the World*. He also took a leadership role in the 2017 March for Science.

One Laptop per Child

One Laptop per Child (OLPC) is a nonprofit organization whose mission is to transform education and empower the children of developing countries by creating low-cost computers for underprivileged schools. OLPC achieved this goal by creating devices as well as software and content for them. OLPC's objective is to transform the learning process by providing a means for exploration, learning, and self-expression to the children of developing nations who have little or no access to education. OLPC believes that children are eager to learn, and those given laptops will have more ability to access information. It is hoped that they will then more fully contribute what they learn to the community.

American architect Nicholas Negroponte is the founder and chairman of the Massachusetts Institute of Technology's Media Lab. Negroponte founded One Laptop per Child while at the Media Lab. OLPC wanted to create low-cost machines, since current computers were too expensive. There were issues with software specs and hardware, but after six years, OLPC completed a laptop. It cost \$200, though it was originally supposed to cost \$100.

OLPC has been praised for providing low-cost machines to children in developing countries. One Laptop per Child reported that “more than 3 million laptops” had been shipped as of 2015. Still, the non-profit faces criticism from representatives of developing countries. Clean water and a lack of schools are prominent issues in these countries, so money spent on technology is not always viewed as a priority. Several African representatives at the World Summit on the Information Society held by the United Nations in 2005 voiced concerns over the motives of the OLPC project. They were suspicious of the “U.S. mindset” of the laptop’s software and programs, and they felt the laptop wasn’t applicable to “African problems.” Uruguay was the first country to purchase a full order of 100,000 laptops in 2007. The laptops have so far cost the state \$260 per child, including equipment repairs, Internet connections, and training for teachers. An information portal for pupils and teachers will be included in the annual maintenance cost of \$21 per child.

Onion Router. See TOR (The Onion Router)

PayPal

PayPal is the world’s largest online payment system, supported with a host of online commercial ventures as the payment processing option of choice.

Peter Thiel, Max Levchin, Ken Howery, and Luke Nosek founded Confinity in 1998. The company specialized in security software, and the founders discovered they needed an in-house money transfer system. John Malloy at BlueRun Ventures funded the company add-on in 1999. A year later, Elon Musk merged his online banking company with Confinity. The company was renamed PayPal in 2001, and Peter Thiel replaced Musk as the company’s chief executive officer. PayPal became a publicly traded company in 2002, and shortly afterward, eBay acquired the company as a subsidiary. Thus began PayPal’s domination of the online payment market.

In the early 2000s, other companies, including Pay Direct, c2it, BidPay, and Google Checkout also offered online payment services. Each company found itself in competition with PayPal, and each company eventually failed. After eight years of business, Paypal had over 100 million user accounts, using 25 different currencies in 190 markets worldwide. Paypal continues to enjoy market dominance, driven by its ease of use for consumers.

PGP Encryption

PGP, or *Pretty Good Privacy*, is a well-known program used to encrypt and decrypt e-mail over the Internet. It is used to authenticate messages with digital signatures and encrypt stored files. It is also the most widely used encryption software available and considered a critical element to online privacy.

The cryptography software PGP was created in 1991 by Phil Zimmermann, a programmer and special director of Computer Professionals for Social Responsibility (CPSR), to promote awareness of privacy issues in a digital age. Even though Zimmermann created PGP, it drew on a long history of cryptographic

discoveries. Cryptography is the writing of messages in secret code. Encryption makes secrecy possible, and PGP was one of the strongest encryption tools available to the public. PGP was originally designed as a combination of RSA (a public key cryptographic algorithm) encryption and a symmetric key cipher known as Bass-O-Matic (a conventional or symmetric) key algorithm, which was later replaced by IDEA because it enabled a more secure encryption technology.

The encryption technology works by using two keys that are required to encrypt and decrypt a secure message; one is public and the other private. For example, if someone wants to send a friend a secure communication, he or she downloads the friend's public key and uses it to send the coded message. The friend's public key has a corresponding private key (which only the friend should have), and this is used to decode the message. When encrypting a message, PGP uses a faster encryption algorithm, which then uses the public key to encrypt the shorter key that is used to encrypt the entire message.

PGP can be used to validate digital certificates and encrypt or decrypt texts, files, e-mail, directories, and so forth. Symantec is one company that offers PGP-based products for encrypting files shared across a network with Symantec File Share Encryption; and for full disk encryption on desktops, mobile devices, and removable storage, it offers Symantec Endpoint Encryption. These Symantec products allow users to decrypt and re-encrypt data via a single sign-on when PGP technology is used for files and drives instead of messages. PGP encrypted e-mail nowadays can be exchanged with other users outside of the United States if both ends have the correct versions of PGP. The original PGP technology went out of date and was bought by Symantec, so now it has been replaced by free software called *GNU Privacy Guard* (GPG or GnuPG).

Plan B. See RU-486/Plan B

Quantum Science

Quantum science is the field of science focused on the smallest components of atoms; it studies how they react to stimuli, deeply involving the disciplines of both engineering and technology. Max Planck, a physicist and creator of the Planck length (the shortest length that can exist) started the quantum revolution in 1900 when he published a paper on black body radiation, a theory that describes how hot objects emit light. Albert Einstein was initially against the explanations of certain quantum phenomena because they did not follow his theory of general relativity, but he eventually began research in the field.

In the 18th century, Isaac Newton first speculated that light traveled in packets of energy that he called "corpuscles," which modern science has renamed "photons." The scientific community at first dismissed Newton's speculation in favor of the widely accepted theory of light as a wave. In 1801, physicist Thomas Young performed an experiment in which light was shined through a barrier with two parallel slits that let the light pass through onto another wall, where the resulting wave pattern could be studied. The interference pattern matched what was expected if light behaved as a wave.

In 1905, Einstein marked the end of what is now called the era of classical physics and the beginning of the quantum era by publishing his findings on the photovoltaic effect, the basic process in which a solar cell converts sunlight into electricity. The photovoltaic effect is what CRT televisions and monitors used to use to display images, but in today's digital world, this effect is concentrated in solar panels. Einstein's finding described light as a particle, as photons hit the electrons out of their atoms. These results indicate a wave-particle

duality, showing that an entity such as light has the properties of both a wave and a particle. This phenomenon is not just a property of light but can be seen in other fundamental particles such as electrons.

In 1920, Niels Bohr created an atomic model of electron energy levels in which the electrons orbit in shells, each shell having its own energy state. As an electron becomes energized, it moves from one energy state to the next. When an electron moves to a lower state, energy is released in the form of light. The wavelength of this light depends on the distance between the energy levels the electron moves through. This theory powers spectroscopy, which has been used since the 20th century to determine the elemental makeup of distant stars by measuring the wavelengths of light emitted from them. For this work, Bohr received the Nobel Prize.

In 1932, Werner Heisenberg was awarded the Nobel Prize for his publishing on the standard proton, neutron, electron model of the atom. His contribution to the quantum world is known as the “Heisenberg uncertainty principle.” This principle states that a particle’s position and momentum cannot both be known. In other words, if the position of a particle is known, its momentum remains a mystery; and so, the opposite is also true. Similarly, in 1933, Erwin Schrödinger received a Nobel Prize for his equations describing how physical states change over time, taking into consideration quantum effects. His “Schrödinger’s cat” thought experiment illustrates the behavior of quantum states, in which all possibilities exist until observed or measured.

In the 20th century, laser light was achieved by implementing a quantum property of the atom, making lasers useful in the medical field for surgical procedures, the construction industry for leveling, the military for tracking, and in the household to read data off CDs, DVDs, and Blu-ray discs. In modern times, computer processors can contain over a billion transistors, which are like gates that allow current to pass through when activated. Bohr discovered the principle behind transistors when he described electrons falling into lower-level orbital shells.

Today, we know that the atom does not completely match the Bohr model, where the electron orbits the nucleus like a planet around a star. Instead, the atom

exists in probability zones, where at any given time, the electron can be found within them. While normal computers operate on a two-bit system, where at any time, the bits can be either a one or a zero, but not both, quantum computers use qubits (quantum bits), which can hold both states at the same time—the superposition of the qubit. With this kind of system, all possible combinations of qubits can exist at once.

RFID Labels

In January 2005, Walmart, the nation’s largest retailer, announced to its top 100 suppliers that radio-frequency identification (RFID) labels would be required on all pallet shipments. Many consider this event the beginning of a revolution in inventory management and package tracking. RFID uses a microchip label to emit radio waves to transfer data to an electronic reader. RFID product tags can accurately update inventory routinely without human labor and in seconds, reducing the time to take inventory, and they help manage the entire ordering and delivery needs of the supply chain. They also make delivery tracking throughout the supply chain easy. In the store, RFIDs offer quick electronic checkout and huge savings are possible by avoiding out-of-stock situations. Commercial experiments are now underway to tie RFID tags with smartphones for credit card purchases and other applications, such as electronic toll collection. While the benefits are huge, problems with the initial costs and privacy and security concerns remain.

The technology of RFID is a confluence of several streams of development. Its earliest roots go back to

The radio frequency identification (RFID) tag can be used as an alternative to bar codes to tag wildlife, identify medical patients, and more. (Vetkit/Dreamstime.com)

the development of electrical transponders to identify planes at the end of World War II. The more recent history is one of miniaturization. The earliest patents occurred in the 1980s; the tags then consisted of a microchip with an integrated circuit for storing, processing, and sending data. Most have a small, built-in battery that can be activated in the presence of a reader or can actively broadcast. Some low-cost ones are passive (having no battery) and are read by a mobile sensor/reader, since broadcasting is presently limited to a few yards. The active battery-powered tags are very expensive (over \$50), and therefore they are applied to larger and more expensive items.

Walmart is one of the few retailers big enough to help push implementation of RFID down the supply chain. However, in 2007, the U.S. Department of Defense (DoD) also requested RFID labels on many of its purchases. The DoD has since mandated it on

most pallet shipments according to MIL STD 129. Walmart's initial 2007 plan was to use smart labels on all pallets going to its stores and Sam's Club. As might be expected, suppliers were not happy and dragged their feet. Sam's Club imposed a threatening \$12-per-pallet penalty, which it later reduced to 12 cents a pallet. Walmart issued a full-implementation target for pallets by 2010, though the target was not reached. Other retailers and wholesalers have joined in on pallet shipments, such as Procter & Gamble. In 2010, Walmart took a larger step in implementing RFID tags on clothing. At the same time, J. C. Penney was experimenting with RFID.

RFID offers potential huge savings in inventory control, reduction of lost sales due to better stocking, and reduction in theft. Walmart studies suggest that out-of-stock situations could be reduced as much as 30 percent, translating into more sales. Inventory control

software has made big advances since the 1990s with material requirement planning (MRP). MRP systems can be a real advantage in inventory management, but they require an accurate physical count to function properly. RFID offers the accuracy to improve the function of MRP and inventory control software. The cost of hand scanning of inventory is eliminated. The ability of RFID technology to instantly provide an updated, accurate picture of inventory on hand and shipments in transit mean large savings. In addition, the impact on theft would be just as big. One problem, however, is concern over privacy and tracking beyond the store. Another is that in-store scanners could access digital codes embedded in credit cards or special driver's licenses.

Applications are expanding beyond retailing as well. Assets can be tagged and readily inventoried at year end. Banks such as Wells Fargo and Bank of America are using RFID tags on information technology assets. One of the earliest uses of RFID included tagging of animals after the outbreak of mad cow disease. Some casinos are using embedded RFID tags on high-value chips to detect counterfeit chips and invalidate stolen chips. One area of research continues to be automatic checkout systems and payment. Today, Intermec Technologies and Symbol Technologies (Motorola) are the major manufacturers. Tag prices are coming down, which will encourage more implementation. Interestingly, the path forward can be found in the implementation of bar code technology.

RU-486/Plan B

RU-486 is the most common type of "morning-after pill" used as an emergency contraceptive by women who have had unprotected sex. It can also be used in the first three months of pregnancy to effect a medical

abortion. It is safe and effective at protecting women against unwanted pregnancies. The approval of RU-486 in September 2000 by the Food and Drug Administration in the United States gave women new levels of control over their bodies. Antiabortion advocates argue against RU-486 and medications like it, saying that they will make abortion more common. National statistics do not bear out this claim.

RU-486 (under the brand name Mifeprex) is a complex chemical that effectively blocks P receptors in the placenta so that fertilized eggs cannot implant themselves, resulting in the termination of pregnancy. In addition, it has been used in the treatment of leiomyomata, endometriosis, advanced breast cancer, and meningioma. It may be used as an estrogen-free contraceptive.

It has been widely, effectively, and safely used in France, Sweden, and Great Britain since the 1980s. Roussel Uclaf, the company that held the RU-486 patent, did not seek approval from the USFDA. In 1995, the company ceded American rights to the drug to the Population Council, which sought FDA approval. Clinical trials in the United States began in 1994 and 1995, and the drug was approved by the FDA in September 2000. RU-486 is used in the United States both as an emergency "morning-after" pill and as a first-trimester (the first three months of pregnancy) medical abortifacient. RU-486 and similar medications can also be delivered by an intrauterine device (IUD) for long-term (up to 12 years) birth control.

In 1999, the FDA approved Teva Pharmaceutical Industries to market an emergency contraceptive set of drugs commonly called "Plan B" to prevent pregnancy. The first pill is taken within 72 hours of unprotected sex and the second 12 hours later. In 2001, the Center for Reproductive Rights and other groups petitioned the FDA to make the drug available without a prescription. Antiabortion advocates argued that the pills would be too accessible to minors, and the FDA ignored the petition, probably to avoid a political storm. In 2006, the FDA first rejected the petition and then later in the year approved it. Plan B could now be sold without a prescription in drugstores. Three years later, Teva Pharmaceutical Industries came out with a one-pill version, or Plan B One-Step.

Planned Parenthood reports that in the wake of *Roe v. Wade* (1973), which legalized abortion in the

United States, 3 of 10 American women will have an abortion before they are 45 years old. More than 75 percent of women who have an abortion say they could not afford the child. RU-486 is also used as a safe alternative to surgical or in-clinic (vacuum aspiration or dilation and evacuation) abortions. Medical abortions are 98 percent effective, though there are rare allergic reactions to the drugs. Medical abortions are less intrusive and more effective than surgical abortions, offering women who do not want to continue a pregnancy a superior medical treatment.

Antiabortion advocates object to all types of abortion and thus object to RU-486. Some antiabortion activists object to abortion when a woman's pregnancy is the result of rape. A small number of conservative antiabortion activists believe that a pregnancy cannot result from rape. Medical science disputes this claim, pointing out that no study has ever found a connection between a woman's desire or reluctance to have a baby and the fertilization of an egg.

While both contraception and abortion remain politically fraught topics, almost 90 percent of Americans believe that contraception is moral and within a woman's rights, and 53 percent of Americans agree with *Roe v. Wade*. Pro-woman advocates point out that women can never have true equality if they cannot control their own bodies and their fertility.

Science Friday

Science Friday is a popular podcast heard weekly by millions of listeners on Public Radio International and on the Internet. It covers topics such as news, nature, science, and technology in an entertaining and informative way. The podcast was created when the National Science Foundation agreed to fund a weekly talk show about science. After the cancellation of National Public

Radio's talk show *Talk of the Nation*, *Science Friday* was spun off as its own radio show. *Science Friday*'s recording takes place in New York, New York. The podcast has a total of 31 staff members. The director is Charles Bergquist, and the executive director is Danielle Dana. The host and executive producer of the talk show is Ira Flatow. Flatow is a science correspondent and a TV journalist. Each staff member is engaged on social media, mainly on Twitter, to give insights on science-related topics and communicate with their fans as well.

Science Friday began in 1991 and is still on the air as of 2018. With 374 public radio stations and 1.3 million listeners, *Science Friday* is the most influential science-based radio show in the nation. Approximately 23 million downloads per year made it one of the most popular iTunes downloads in 2017.

Not only does the program provide information on topics such as science, nature, and technology, but so does its Web site, www.sciencefriday.com. The site offers entertaining educational materials and original videos for the fans to learn new information on whatever topics are being covered. Also, the talk show has interesting segments where authors and scientists discuss their newsworthy achievements.

With millions of audience members tuning in to *Science Friday*, the podcast has achieved awards and recognition for high-quality journalism.

SETI (Search for Extraterrestrial Intelligence)

The Search for Extraterrestrial Intelligence (SETI) is an organized effort to detect alien communications. SETI researchers have concentrated their efforts in specific areas of the sky. Although SETI was begun by one

man, over time, technological innovations have helped make it a group effort. Advancements have also helped researchers scan in better and new ways. Although SETI researchers have uncovered a few unexplained signals over the years, they have yet to conclusively confirm the existence of alien intelligence.

In 1959, physicists Giuseppe Cocconi (1914–2008) and Philip Morrison (1915–2005) published a paper in which they stated that radio signals within a range of 1 to 10 gigahertz would be best for interstellar communications. That same year, astrophysicist Frank Drake (1930–) established the first SETI program. Drake garnered support from the scientific community for the search with his Drake equation, which is a way of estimating the number of communicative extraterrestrial civilizations that may exist in a galaxy. By the early 1960s, another SETI program was established at The Ohio State University (OSU). OSU professors and students used “Big Ear,” a 360-foot-wide, 500-foot-long, and 70-foot-high radio telescope to listen to distant stars.

In the late 1960s, the National Aeronautics and Space Administration (NASA) began supporting search initiatives. NASA scientists devised several SETI-related programs, including the Microwave Observing Project, Project Orion, and the High-Resolution Microwave Survey. Although NASA functioned in a supportive capacity from the 1960s to the 1980s, its direct involvement in SETI was minimal. In contrast, in 1992, NASA began an intensive SETI program. It lasted only one year, because the U.S. Congress cut its funding.

Since that time, SETI initiatives have relied heavily on private funding and volunteer participants. SETI has evolved into several different groups with slightly different approaches to the same objective. The development of new technologies has nurtured a team approach to the search. For example, since 2004, more than 5 million volunteers from around the world (from over 200 countries) have collectively donated millions of years of computer data analysis time. Since 2006, the University of California, Berkeley sponsors SETI@home, which is a distributed computing project. Data collected at the Arecibo Radio Observatory (ARO) is sent to Berkeley, where it is then divided into units that are sent to personal computers around the

world. Each volunteer then spends many hours examining the individual unit, looking for possible alien radio signals. If a volunteer believes he or she has found a candidate signal, it is sent back to Berkeley for further analysis.

Other Berkeley SETI initiatives include the Search of Extraterrestrial Radio Emissions from Nearby Developed Intelligent Populations (SERENDIP), Southern SERENDIP, and Optical SETI. In addition to ARO, Berkeley also has access to the Allen Telescope Array (ATA), an array of antennas equivalent to a single enormous dish. Project Phoenix uses a receiver that is much more sensitive than other SETI radio telescopes. The state-of-the-art receiver is capable of amassing radio energy for longer periods, and the clearer radio wave picture allows scientists to analyze data faster and more precisely. Other innovations have allowed some projects to search within more regions of the electromagnetic spectrum.

The observable universe is vast and expanding. By 2017, astronomers had observed evidence of the existence of more than 100 billion galaxies in the universe. NASA scientists theorize that that number will increase significantly as Earth’s telescope technology improves. In addition, scientists have speculated about the existence of many more galaxies beyond the earth’s light horizon (the point at which light from distant stars has reached the earth), which will remain unobservable by any means as the universe continues to expand. Our own Milky Way galaxy measures approximately 100,000 light years in diameter, and it contains more than 100 billion stars. Many of those stars have planets that orbit them.

Present-day technology precludes humans from physically traveling to distant galaxies to explore them. In fact, even our own galaxy’s vastness renders unmanned probes impractical for its complete exploration. Radio waves, which have been in use for a little over a century on earth, travel at the speed of light. This means that to date, Earth’s earliest radio signals have only reached about 100 light years into our galaxy. However, even though Earth’s radio signals presently have a comparatively limited range, the radio signals of other, much older planets may theoretically reach Earth. This expectation (or hope) serves as the incentive for SETI participants.

Due to the vastness of the search area, SETI participants have narrowed their searches based on certain assumptions (that may or may not be accurate). The first assumption is that a star similar to the earth's sun is necessary for any kind of life to evolve on an alien planet. The second assumption is that the presence of an Earth-like sun and water on a planet is necessary for the development of intelligent life. Using these two assumptions as their criteria, SETI participants have estimated that 10 percent of the stars (about 1,000) in our galaxy are similar to our sun. Consequently, SETI participants have concentrated most of their attention in these areas.

The most famous unexplained signal ever found by SETI occurred on August 15, 1977, when astronomer Jerry Ehman wrote the word, "WOW!" on the margin of a computer printout he was examining. Since that time, countless efforts have been made to recapture the same signal. For example, SETI used the ATA to collect 100 hours of new data from the same direction of the WOW! signal, but nothing was found. The null result did not deter SETI researchers. In fact, SETI observations of the same area of space are still in progress. Many SETI participants still regard the WOW! signal with awe. On August 15, 2017 (40 years after the event), the official SETI Institute Web page posted, "Happy Birthday WOW!"

In 2016, Antonio Paris, a professor of astronomy at St. Petersburg College in Florida, reported that a comet was likely responsible for the mysterious signal. Paris stated that the signal was a match for a signal emitted by a more recent passing comet. Although it was impossible to determine if the comet he had observed was the same one that might have caused the irregular reading 40 years before, he was certain that the WOW! signal was not the product of alien intelligence. Paris confessed to be disappointed by his finding.

After searching for more than half a century, SETI has yet to find conclusive proof of intelligent extraterrestrial life. Some scientists have contemplated a few possible reasons for this phenomenon. Perhaps the assumptions that SETI scientists have made in determining where to search have been incorrect. Perhaps alien civilizations do not exist, and Earth is a solitary anomaly. Or, Earth may be the first intelligent civilization to

emerge among many more that may come later. In these two previously described scenarios, there would be no messages for Earth to find. According to the Drake equation, not all intelligent life forms may have discovered radio waves, or they may not be willing or able to communicate with Earth. A doomsday-type scenario states that all intelligent life may annihilate itself after reaching a certain level of technological advancement, and therefore, radio signals that may one day reach Earth may be from a civilization that no longer exists. Finally, even if a planet contains a thriving civilization, it may be too far away from Earth for its radio waves to reach us.

In spite of these possibilities or any other obstacles, the SETI community seems as determined as ever to keep searching. In recent years, only about 50 percent of the visible sky had been scanned more than once, and 10 percent of the visible sky had still not been scanned at all. The development of NASA's Kepler space telescope allowed astronomers a much better view of the universe, because its lenses were not obstructed by Earth's atmosphere. Kepler has aided astronomers in the discovery of new planets that orbit suns. These discoveries have given SETI a greater range of target search areas. In addition, many radio frequencies are still unexplored. In truth, even a thousand years of searching would be a drop in the bucket given the vastness of the search area. It remains to be seen how the development of new technologies will both reshape the SETI organization and enable a better view of the scannable sky.

Smartphone and 3G Network

The 3G network, as the third generation in mobile telecommunications is known, has a complex history because some of the engineering advances that define a third generation are subjective. This third generation of telecommunications was driven more by standards and network protocol than by technology and meets the international specifications, called International Mobile Telecommunications-2000 (IMT-2000), of the International Telecommunications Union. This wireless communications network supports a wide range of devices such as smartphones, mobile laptops, videophones, and mobile television. Japan was the first to launch a true 3G network in 2001. The standard allows for more broadband efficiency than 2G and speeds of 6 to 15 megabits per second to support smart devices, although technically, the standard requires peak data rates of only 380 kilobits. The 3G networks use different radio frequencies than 2G does. 2003 stands out as the year of American 3G networks, or mobile broadband, when Verizon and AT&T (Cingular at the time) introduced their 3G networks. The arrival of 3G expanded the use of cell phone devices into video e-mail, mobile television, movie watching, Internet surfing, and video conferencing.

In late 2003, Cingular had its 3G wireless network ready, but it needed a breakthrough device to push network use and profits. The very first 3G phones to hit the market in 2003 were heavy and large; they were very unpopular. Wireless companies looked for a manufacturer to popularize 3G, but they wanted complete control. Their voice phone business was peaking, and profit margins were declining. The 3G network offered the potential for high-profit-margin data users to download music, books, and videos and to surf the

Internet. Wireless phone carriers such as Cingular and Verizon had gotten used to defining the devices to be used. Steve Jobs at Apple Computer was looking at a much different relationship in the development of a multiuse cell phone of the future. Apple had already successfully moved into the MP3 music market with its iPod. Jobs envisioned a single device to function as an Internet, music, and phone device. It was the perfect utilization of the 3G technology.

In 2005, Jobs launched a team of 200 engineers on the iPod development project while he started secret negotiations with Cingular. Jobs realized that competitors were watching, and he wanted to assure secrecy. This was a major breakthrough, and he well remembered how Microsoft had pirated his operating system. He spread out his team members and separated his hardware and software teams. Visits to Cingular were kept secret, and members signed in as employees of Infineon. He also had developed an advanced touch screen for his failed PC tablet that competitors still had not duplicated, and he planned to use it in his new iPhone. The whole time, Jobs publicly denied that any work was being done on a cell phone. But Apple was working with Motorola and Cingular on a music phone to be released in 2005 known as “ROKR.” The ROKR, with an Apple operating system and supported by its iTunes library, did come out in late 2005. The 2007 release of the iPhone made the ROKR obsolete. The iPhone was able to hold 1,500 songs versus 100 for the ROKR. The ROKR also had a bulky, walkie-talkie-like appearance, which added to its unpopularity. The June 28, 2007, release of the iPhone was an amazing testament to Apple’s market following. Estimates of sales for the first weekend were as high as 700,000.

The development of the iPhone was the perfect combination of Apple’s search for a high-profit device and the carriers’ search for a breakthrough application. The competition between carriers such as Verizon and AT&T (which purchased Cingular at its peak in 2006) allowed Apple to take leadership in the manufacturing and design of the new generation of cell phones. Jobs found himself in the driver’s seat with his proposed iPhone. Jobs wanted to break the earlier cell phone model where cell phone manufacturers profited on the

sale of the devices rolled into a time-specified contract. Jobs wanted higher profit margins and to profit from the usage as well. Negotiating with AT&T, which at the time was losing market share to Verizon, Jobs had huge leverage. The iPhone could offer a huge flood of new customers. Jobs even pushed AT&T (Cingular) to assure video e-mail over the network. Jobs also demanded complete commercial and manufacturing control over the iPhone, and he got what he wanted. Apple would make a profit of about \$150 on the initial selling price of \$599 and \$10 a month from every AT&T bill on a two-year contract. Even after the initial price was reduced to \$399, Apple still made \$80 per phone.

The iPhone business model caused manufacturers to design for customer approval rather than for carrier approval as had been the case in the cell phone business model up until then. Prior to the iPhone, carriers determined the prices and features of the phones being offered. The results lived up to every hope and dream of Apple. It sold over 3 million phones in the six final months of 2007, returning more than the estimated development cost of \$150 million. Google's Android phone came into the market because of the exclusive initial deal with AT&T. The iPhone created a whole new industry of phone applications to develop all of the iPhone's capabilities. Carriers that lost their control over wireless devices were even looking at wireless banking to expand their services along with the iPhone's capability.

The expansion of 3G networks rejuvenated the stalled technology of electronic books with devices such as Amazon's Kindle. These 3G electronic books redefined the selling of books and accelerated the decline of brick-and-mortar stores. 3G proved to be a major commercial advance, more so than the first two generations of wireless communications.

Tarter, Jill (1944–)

Jill Tarter is an astronomer and cofounder of the Search for Extraterrestrial Intelligence (SETI) Institute in California. Tarter is currently the holder of the Bernard M. Oliver Chair for SETI. She has dedicated her career to the search for extraterrestrial life outside of our solar system.

Tarter was born on January 16, 1944. As a child, Tarter was always more into male-dominated activities than other girls her age. Her father taught her about constellations and the sky at night. Tarter always wondered if humans were the only ones in this universe, which is why, at eight years old, she decided to be an engineer.

Tarter is a descendant of Ezra Cornell, the founder of Cornell University. As an adolescent, Tarter wanted to attend Cornell. Unfortunately, her family couldn't afford to send her to college. The only way she could attend was to win scholarships. She applied for a scholarship specifically for descendants of Cornell but was not eligible because it was only given to males. Tarter was accepted into Cornell through a different scholarship, but she was the only woman in a class of 300 engineering students. Tarter received her bachelor's degree in engineering physics and later received a master's and PhD in astronomy from the University of California, Berkeley.

In graduate school, Tarter was involved in projects that were specially designed to find radio frequencies that might come from alien life forms. This project was part of SETI, which was very small at the time. Tarter enjoyed the projects and studies so much, she decided to dedicate her life to SETI and become a guiding force behind it. Tarter was a part of a project called Project Phoenix, where the SETI Institute performed a decade-long experiment observing 750 star systems. SETI sent radio signals out from Puerto Rico, West Virginia, and Australia. No sign of extraterrestrial life was found, but this was Tarter's biggest project ever in trying to find evidence of life outside of what we know on Earth. Tarter was one of the first women to pioneer our search for extraterrestrial life.

Tarter's work and dedication to her career have brought her many awards, including the Lifetime Achievement Award from Women in AeroSpace. She

Jill Tarter, at the SXSW Music, Film and Interactive Festival in 2013. Tarter is a vigorous proponent of science education. (Rita Quinn/Getty Images for SXSW)

was named one of *TIME* magazine's 25 Most Influential People in Space. She received two Public Service Medals from NASA, the TED Prize in 2009, and Silicon Valley's Women of Influence Award in 2010. Asteroid 74282 Tarter was named after her. She was also listed in *TIME* magazine's 100 Most Influential People in the World in 2004. In 2012, Tarter stepped down from SETI after 35 years. Gerry Harp, who is a physicist at the SETI Institute, became its next research director. Although Tarter is now retired, she dedicates her time to hosting fundraisers for SETI's current work.

Thompson, Ken (1943–)

Ken Thompson is the computer scientist who created the Unix operating system and the C language with Dennis Ritchie. In 1983, he shared the A. M. Turing Award given by the Association for Computing Machinery for contributions of lasting and major technical importance with Dennis Ritchie for inventing the Unix operating system at Bell Laboratories.

One of the most important advantages of Unix is its clean and simple interface. Also, Unix was shared freely with universities early on, so students could adopt it quickly. Unix is very important in the history of computer science because it is the backbone of the computerized technical infrastructure of the modern world.

Thompson was born in 1943 in New Orleans, Louisiana. He was always interested in studying logic and liked to solve arithmetic problems in binary. He received his bachelor's and master's degrees in electrical engineering from the University of California, Berkeley (UCB). He was then hired by Bell Labs, where he participated in a project called the Multiplexed Information and Computing Service (MULTICS). Eventually, the project grew too complex to control, and it was vulnerable to criminal hackers. For this reason, Bell Labs stopped the project.

Thompson worked on Unix, which began as a scaled-down version of the MULTICS. In 1969 he created a game called *Space Travel* that helped pilots practice flying in space just as humans first went to the moon. It was not only the first computer game but the first application to run on the Unix operating system. In the process, he gained a better understanding for the development of Unix. One of the most important factors for his success was his PDP-7 computer, which was the first to run his operating system. It had an 18-bit word length and only four kilobytes of memory. Because it had such a small memory, Thompson needed to keep his operating system small. In other words, his philosophy of simplicity arose because the PDP-7 was not a powerful-enough computer to run a complex operating system.

In 1970, Thompson wrote a programming language called B, which was the basis of the Basic Combined Programming Language (BCPL). Dennis Ritchie then wrote another programming language based on B, calling it "C" in the spirit of Thompson's philosophy of simplicity.

In 1972, Thompson rewrote Unix in C, which made it more portable and therefore successful. After he published his operating system, he returned to the university as a visiting professor. A lot of changes in the computer industry followed, and many start-ups such as Solaris, HP-UX, and AIX used Unix. Several functions in Unix worked well for start-ups, the most important being that it was designed to handle multiple users connected to a single network so they could share information. So, the Unix operating system had a great impact not only on computer science, but also in the business and scientific sectors.

In 1983, after Thompson became a fellow at Bell Labs, he kept working on new operating systems, such as Plan 9 and Inferno, also with Ritchie. For this and other great achievements, Thompson and Ritchie were awarded the U.S. National Medal of Technology as Unix inventors in 1998. Thompson also won the IEEE Richard W. Hamming Medal in 1990; he was made a fellow of the Computer History Museum in 1997 and won the Tsutomu Kanai Award in 1999 and Japan Prize in 2011.

After he retired from Bell Labs in 2000, Thompson moved to California and worked at Google as a distinguished engineer.

Primary Document: Interview with Ken Thompson, Inventor of the UNIX System (2011)

This interview with Ken Thompson, inventor of the Unix operating system, was conducted by Andrew Binstock of the Open Source section of the Dr.

Dobb's Web site after the ceremony presenting Thompson with the Japan Prize, which showed the international importance of Unix. They also discuss

Thompson's work designing the Go language for Google and how he collaborated with Dennis Ritchie and Ritchie's role in developing Unix.

Interview with Ken Thompson

By Andrew Binstock, May 18, 2011

The creator of UNIX discusses writing UNIX, the Go language, and collaborating with Dennis Ritchie

The Japan Prize, one of the highest honors awarded for outstanding contribution to science and technology, was awarded jointly this year to Ken Thompson and Dennis Ritchie for the creation of UNIX. The prize is normally given to the recipients at a lavish banquet in Tokyo attended by the emperor. However, due to the April earthquake and tsunami, the prizes this year were distributed at the honorees' place of work. I was able to attend the ceremony for Ken Thompson, held at Google headquarters, where he currently works. After the ceremony, he consented to this exclusive interview.

DDJ: Congratulations on winning this prize.

KT: Thanks.

Developing UNIX

DDJ: You've received a lot of awards over the years for UNIX. At what point in UNIX's development did it become clear it was going to be something much bigger than you'd anticipated?

KT: The actual magnitude, that no one could have guessed. I gather it's still growing now. I thought it would be useful to essentially anybody like me because it was not built for someone else or some third party. That was a pejorative term then. It was written for Dennis and me and our group to do its work. And I think it would have been useful to anybody who did the kind of work that we did. And therefore, I always thought it was something really good that was going to take off.

Especially the language [C]. The language grew up with one of the rewritings of the system and, as such, it became perfect for writing systems. We would change it daily as we ran into trouble building UNIX out of the language and we'd modify it for our needs.

DDJ: A symbiosis of sorts . . .

KT: Yeah. It became the perfect language for what it was designed to do. I always thought the language and the system were widely applicable.

DDJ: In the presentation today, it mentioned that UNIX was open source. Was UNIX open source from the beginning?

KT: Well there was no such term as "open source" then.

DDJ: I was under the impression that UNIX really became open source with the Berkeley distribution.

KT: No, we charged \$100, which was essentially the reproduction cost of the tape, and then send it out. And we distributed, oh, probably close to 100 copies to universities and others.

Go Language

DDJ: Skipping several decades of work, let's speak about Go. I was just at the Google I/O Conference, where it was announced that Go will be supported on the Google App Engine. Does that presage a wider adoption of Go within Google, or is it still experimental?

KT: It's expanding every day and not being forced down anybody's throat. It's hard to adopt it to a project inside of Google because of the learning curve. It's brand new and there aren't good manuals for it, except what's on the Web. And then, of course, its label of being experimental, so people are a little afraid. In spite of that, it's growing very fast inside of Google.

DDJ: In the presentation before the awarding of the Japan Prize today, you were quoted on the distinction between research and development. [The former, Thompson stated, was directionless, whereas development had a specific goal in mind.] So in that context, is Go experimental?

KT: Yes. When the three of us [Thompson, Rob Pike, and Robert Griesemer] got started, it was pure research. The three of us got together and decided that we hated C++. [laughter]

DDJ: I think there'd be a lot of people who are with you on that.

KT: It's too complex. And going back, if we'd thought of it, we'd have done an object-oriented version of C back in the old days.

DDJ: You're saying you would have?

KT: Yes, but we were not evangelists of object orientation. [Returning to Go,] we started off with the idea that all three of us had to be talked into every feature in the language, so there was no extraneous garbage put into the language for any reason.

DDJ: It's a lean language, indeed.

Collaboration with Dennis Ritchie

DDJ: Returning to UNIX, for a moment, when you and Dennis worked together, how did that collaboration operate? Were you working side by side?

KT: I did the first of two or three versions of UNIX all alone. And Dennis became an evangelist. Then there was a rewrite in a higher-level language that would come to be called C. He worked mostly on the language and on the I/O system, and I worked on all the rest of the operating system. That was for the PDP-11, which was serendipitous, because that was the computer that took over the academic community.

DDJ: Right.

KT: We collaborated every day. There was a lunch that we went to. And we'd talk over lunch. Then, at night, we each worked from our separate homes but we were in constant communication. In those days, we had mail and writ (pronounced 'write'), and writ would pop up on your screen and say there was a message from so-and-so.

DDJ: So, IM essentially.

KT: Yes, IM. There was no doubt about that! And we discussed things from home with writ. We worked

very well together and didn't collaborate a lot except to decide who was going to do what. Then we'd run and very independently do separate things. Rarely did we ever work on the same thing.

DDJ: Was there any concept of looking at each other's code or doing code reviews?

KT: [Shaking head] We were all pretty good coders.

DDJ: I suspect you probably were! [Laughter]

SCM

DDJ: Did you use any kind of source code management product when working together?

KT: No, those products really came later; after UNIX. We had something like it, which we called "the code motel" because you could check your code in but you couldn't check it out! So, really, no we didn't.

DDJ: I bet you use SCM today in your work on Go.

KT: Oh, yes, Google makes us do that!

3-D Printing

3-D printing is the process of creating a three-dimensional object from a template originally designed using a computer program and formed by applying thin layers of material onto one another in quick succession. Objects can be printed in almost any shape or geometry. Another term for 3-D printing is "additive manufacturing" (AM). This is the official term used by the United States and global technical standards to encompass the wide variety of techniques. There are seven defined categories of additive manufacturing processes: binder jetting, directed energy deposition, material extrusion, material jetting, powder bed fusion, sheet lamination, and vat photopolymerization.

Additive manufacturing began in the 1980s when Hideo Kodama of Nagoya Municipal Industrial Research Institute invented methods for fabricating plastic models with photo-hardening polymer by a means of UV exposure controlled by a mask pattern.

In 1984, Alain Le Méhauté, Olivier de Witte, and Jean Claude André filed a patent for this process, which was called "stereolithography." However, it was abandoned due to lack of business perspective. That same year, Chuck Hull of 3D Systems Corporation filed his own patent for the process. Hull's is known for his STL (stereolithography) file format and digital slicing and infill strategies. This method is still used in almost all processes today.

Scott Crump later developed fused-deposition modeling (FDM) in 1988, which involves a special application of plastic extrusion. This is the most common hobbyist and consumer-oriented process. Crump's company, Stratasys, commercialized this process and marketed the first FDM machine in 1992. Since then, metal sintering or melting has been developed along with many other AM techniques.

3-D printing uses three general principles. Modeling, the first principle, uses a computer-aided design (CAD) package, plus a 3-D scanner or a plain digital camera and photogrammetry software. CAD models

have the inherent benefit of reduced error and can be corrected before printing. Printing is the second principle and involves several steps. First, an STL file is created from the CAD model, which is processed into several layers using software, called a “slicer,” into a G-code. The G-code file can then be printed. Printer resolution is described by the layer thickness and X-Y resolution in dots per inch (dpi) or micrometers (μm). The final principle in 3-D printing is finishing. Finishing involves cleaning up the final build. “Final build” describes the entire print created by the machine, including the part and all support material used by the printer. Finishing involves the process of removing build supports, smoothing surfaces, or any other final work done to a 3-D printed object.

The main differences between the various AM processes is the way that layers are deposited to create the specific part. One of the main methods melts or softens the material to produce the layers. This method is known as “fused filament fabrication,” another term for FDM. FDM parts are built by the extruding of small beads or streams of material that harden immediately into a layer. Filaments consist of thermoplastic, metal wire, or other material that can be fed into an extrusion nozzle. FDM is restricted in the variation of shapes due to the build method. The nozzle lays a layer of material down and then moves upward in the working area. This leaves the next layer unsupported on overhangs so that the nozzle is printing on air instead of on top of another layer.

Laser sintering techniques include selective laser sintering and direct metal laser sintering. Selective laser melting completely melts metal powder using a high-energy laser; this creates a dense material. Its mechanical properties are similar to conventional manufactured metals. Electron beam melting (EBM) is a similar technique used for metal parts such as titanium alloys. EBM works by melting metal powder with an electron beam in a high vacuum. A thin layer of metal powder is raked off the previous layer, and the electron beam melts the powder into the desired design. This leaves a metal “cake” at completion of the build that needs to go through a finishing process to remove all remaining unfused powder.

Photopolymerization is another type of AM process that produces a solid part from a liquid polymer.

This requires a special type of photopolymer that is cured with UV light. Ultrafine details can be created with this method because the gel is cured to a solid only in the location where the laser is focused. All other gel is washed away. The continuous liquid interface production begins with a vat of photopolymer resin, with the bottom of the vat being transparent to expose the material to UV light. The object is slowly pulled out of the vat layer by layer.

AM has many applications and uses in all different fields of study. Today it is used in industries such as aerospace, architecture, automotive, defense, and medical replacement. The earliest application and most common is rapid prototyping, which allows a reduced lead time and cost of developing prototypes for new parts and devices. In the 2010s, AM entered the production phase for industry. Many companies are looking into the quality and certification of AM parts for production, such as General Electric, which uses high-end AM to build parts for turbines. It is believed that with certification of AM, the complexity of parts can be increased to reduce material, weight, lead time, and cost. This would also reduce maintenance time for replacement parts due to the rapid production time. The medical field is also looking into bioprinting technology, which involves printing layers of living cells into a gel medium to build organs, including vascular systems, with a patient’s own cells. 3-D printing has also improved STEM education due to low cost and high-quality equipment for students.

AM has many applications and benefits but is still in the research stages. Developing the test standards and certification of parts seems to be the biggest challenge faced by industry.

3G Network. See Smartphone and 3G Network

TOR (The Onion Router)

The Onion Router, more commonly known by its acronym, TOR (or Tor), is free anonymizer software. Tor increases anonymity when sending and receiving packets through its network at the expense of packet-sending speed. Tor is free to access and requires a specialized browser, available for free online, to connect to the network.

The Tor network uses an implementation of onion routing, which encrypts a packet with several layers and then bounces the data across randomized servers in the Tor network. Each of these servers uses its own asymmetric encryption, by which the packet is encrypted layer by layer by the user. As the packet traverses the Tor network, each server decrypts the layer it is responsible for and forwards it to the next node; therefore, any individual server does not know the contents of a packet and only knows the server that forwarded the packet to it and the server that it will forward the packet to, allowing for more secure packet sending at the expense of response time. This continues until the packet reaches a Tor exit node, where the packet is fully decrypted and sent to its end server. Due to the number of nodes being relayed through, while it is still possible, it is highly unlikely for someone to be able to pinpoint the origin of a packet sent.

The Onion Router was first released by the U.S. Naval Research Laboratory on September 20, 2002. This Tor was originally based on a paper done by Cambridge researchers in 1996 on packet hiding, eventually leading to the development of onion routing. The Tor network has servers run by volunteers around the globe, numbering in the thousands by 2017.

Today, the Tor network increases anonymity for end users and end servers as well. There are specific domains accessible only through the Tor network. Top-level domain names under “.onion” are onion links accessible only through Tor browsers. These sites reply with packets that are also sent through the

same Tor network, making it difficult to track the origin of the Web sites and shut them down. Due to this nature, Tor is home to many licit and illicit usages. This includes sites that offer free books, political activism, drug trafficking, illegal gambling, and more. Many of these services are often used in conjunction with BitCoin to maintain anonymity online through the use of cryptocurrency.

Tor provides refuge for both censored information and illegal trafficking. Law enforcement has been successful in tracking down several users due to mistakes by end users that break their anonymity. Since Tor exit nodes are publicly listed, it is possible to eavesdrop on a Tor exit node that is not properly secured with end-to-end encryption, resulting in possible leakage of user-related information such as e-mails and passwords.

Torvalds, Linus (1969–)

Linus Torvalds is a software engineer who created the Linux kernel operating system. Because he wrote Linux at the age of 21, people called him a creative genius. Linux is freely available and has had a great impact on the development of shared software and networking. Since its creation more than 20 years ago, Linux has become the world’s most ubiquitous operating system. It has had a great deal of influence on most tech companies, such as Amazon, Facebook, Google, and Twitter. Torvalds became one of the most famous

software programmers, listed several times in *TIME* magazine’s “Most Important People of the Century.” He has won many awards, including the Millennium Technology Prize, one of the largest prizes in the computer field.

Torvalds was born in Helsinki, Finland, on December 28, 1969. When his parents divorced, he lived with his mother and grandparents. Because his mother worked, he spent most of his time with his grandparents. Many in his family were journalists, which influenced him to read a lot, and when he was 11 years old, he started using a computer. His grandfather was a professor of statistics at Helsinki University, so he began using a computer as a programmable calculator.

Torvalds attended the Helsinki University of Technology, where he learned engineering-oriented computer science. He started working on Linux in spring 1991 after learning about Unix and the C language. Wanting to study Unix, he purchased the Intel 80386-based IBM PC and obtained a MINIX operating system to work with. From there, he developed the Linux operating system. It took eight years for Torvalds to receive his master’s degree in computer science since he had a vibrant social life and because universities are essentially free in Finland, so he didn’t have to worry about its costs. But because he did not want to stay in school forever, he thought about his future and went to the United States.

In 1996, he visited the technology firm Transmeta and joined it the following year. He felt he could do something great there. He worked in a group called the 86open from 1997 to 1999, creating binary compatibility across all Unix variants on Intel architecture. In other words, the group focused on building a single application that ran on all Intel-based Unix machines. After he finished the project, he was offered stock options for his creation by the companies Red Hat and VA Linux. After these companies went public, the stocks’ value increased to about \$20 million. In 2006, Torvalds wrote about 2 percent of the Linux kernel, which was a high achievement. And because the Linux kernel is open source, other programmers contributed to write the rest of it. Torvalds received the Millennium Technology Prize in 2012 for his achievements.

In 1993, Torvalds married Tove Torvalds, who was a six-time Finnish national karate champion. They

have three daughters: Patricia Miranda, Daniela Yolanda, and Celeste Amanda. He wanted his daughters to get a good education in the United States. He has said that he is very happy in the United States because his family is. He may be one of the greatest computer scientists in the world, but he is also just a father who loves his family.

Tyson, Neil deGrasse (1958–)

Astrophysicist, science communicator, and author Neil deGrasse Tyson has authored more than 10 books, his most recent being *Astrophysics for People in a Hurry* (2017). Tyson’s books discuss many areas of science in a whimsical and accessible way for the public. His accolades include the NASA Distinguished Public Service Medal and the Public Welfare Medal. Most of his work is focused on astronomy, cosmology, stellar formations, and stellar evolution. He has received much recognition at the government level as well. In 2001, President Bush selected him to be on commission for future advancements in the United States aerospace industry.

Tyson became a household name in 2004 when he hosted a four-part mini television series titled *NOVA: Origins*. In it, Tyson attempted to convey how the universe came to be and where it may be headed in both an interesting and accessible way. Three years later, in

Among the best known public scientists of the 21st century, astrophysicist Neil deGrasse Tyson is a powerful voice for climate change, science education, and space exploration. (Rick Kern/WireImage/Getty Images)

2007, he became a regular contributor on the television series *The Universe* on the History Channel.

Tyson was born on October 5, 1958, and grew up attending public schools in the Bronx neighborhood of New York City. He attended several colleges in the United States, earning a bachelor of science in physics at Harvard University in 1980 and a PhD in astrophysics in 1989 at Columbia University. At age nine, he visited the world-renowned Hayden Planetarium at the Rose Center for Earth and Space in New York City, and his fascination for astronomy began. The center is part of the American Museum of Natural History, and in 1996, Tyson became the fifth head of the Hayden Planetarium. A year later, he founded the Department of Astrophysics at the Museum of Natural History.

Tyson is often linked with late astronomer and cosmologist Carl Sagan. When Tyson was 17, Sagan took him around the Cornell University campus and

gave him a book with an inscription to “the future astronomer.” Tyson has been open about how much this experience with Sagan influenced his life and passion for astronomy. Sagan is famous for a television series that appeared in 1980 and inspired its audience’s fascination with the universe and its beauty. In fact, in 2014, Tyson revived Carl Sagan’s *Cosmos: A Personal Voyage* series through his *Cosmos: A Spacetime Odyssey*. Tyson attempts to inspire passion for the universe the same way Sagan did in his generation. *Cosmos: A Spacetime Odyssey* won many awards, including a Peabody, four Emmys, and two Critics Choice Awards.

Tyson continues to be an active contributor to the astronomy field. He lives in Manhattan with his wife, Alice Young (they married in 1988), and their two children, Miranda and Travis.

Video Game

A video game is an electronic game in which a user interacts with an input device to generate visual feedback on a television screen, computer, or handheld or cellular device. Video games are played on electronic systems, and many of these systems are known as “platforms.” Platforms can differ between computers, gaming consoles, handheld devices, cellular phones, arcade machines, and so on. Due to the affordability of gaming consoles, there has been a decline in the popularity of arcade machines. Gaming consoles can also offer the advantage of being all-in-one entertainment media centers.

Video games use different input devices to generate visual feedback. The input device used is called a gaming controller and can differ between platforms. Common gaming controllers include gamepads, joysticks, keyboards, steering wheels, touch screens, buttons, or visual sensors—even a person’s own body.

Video games are not only visual but also incorporate music, vibration, and story to immerse the user. Users can also wear virtual reality goggles to allow a full immersion into a video game.

Commercial video games first started to appear in the 1970s, but the earliest evidence of a video game dates back to 1947. Video games became very popular with the success of the Atari home console system and the video game *Pong*. Video games soon thereafter left the arcade and began to enter the home as video game platforms became more affordable. Video game consoles now offer more features than just games. Video game platforms or consoles include DVD capabilities,

applications, and online video streaming. They have become all-in-one entertainment devices.

A “platform” is the combination of electronic hardware and software for playing video games. The term “system” can also be used instead of platform. Other important vocabulary in the video game world includes:

- *Personal computers or PCs*, which can be used as platforms to play a video game. A video game may be referred to as a “computer game” to convey that it is played on a PC. Personal computers offer some advantages over other platforms, which may include online gaming, modding, flexibility, emulation, and cost.
- *Consoles*, which are platforms on which video games can be played. Consoles offer the advantage of being home entertainment centers or media centers for the user.
- *Handheld* platforms are small and lightweight. They offer a mobile gaming experience.
- *Arcade* machines are platforms that were mainly popular during the 1980s and have slowly been replaced by consoles. Arcade machines each usually feature only one type of game and can sometimes involve prizes.
- *Mobile* platforms have been increasingly popular due to the rise of cellular phones. Mobile games are usually featured on iOS or Android devices.
- *Virtual reality* headsets are used to experience a fully immersive environment.
- *Genres*. Video games, just like movies, come in different genres offering different experiences and are based on gameplay rather than story or setting.
- *Controllers* are input devices to transmit the user’s actions or intentions into the video game. Controllers differ based on platform. The most widely used controllers are keyboards, mice, gamepads, buttons, or touch screens. Controllers can also be for very specific purposes such as driving wheels, dance pads, or joysticks.
- *Development*. Video game developer roles have increased as video games have become more popular.

In the early days of video games, a single developer would create every element of a game. While this

is still common for small or mobile games, most games are now the products of large development studios. The roles of video game developers can include programmer, graphic designer, sound designer, musician, producer, and so on. The development of games can continue past the games' release date as more content can be made available via download, which can include new story lines, game features, or settings.

Some video games also allow modifications to be made to the game to add new features or interest. Modifications have become extremely popular in PC games and may contribute to the success of a game. Game developers have also created development tools to assist the video game community in creating modifications. In some cases, the modifications of certain video games have led to the creation of entirely new video games.

Glitches are errors that were not detected during testing and end up in the released versions of the video game. Glitches can range from game exploitations, game malfunctions, or minor errors. Glitches are usually reversed in future updates or become additional game features.

Easter eggs are hidden messages, jokes, games, or signatures left by the developers within the game. Easter eggs are often kept hidden by the developers and are left to be found by the video game community.

Emulations are software programs that allow video games to be run on different hardware than the originally intended console. Emulators can be used on PCs, smartphones, and consoles. Video game manufacturers have also made their own emulators to combat video game piracy.

While the main demographic of video gamers have been men, the gap between women and men gamers has decreased. Women over the age of 18 are becoming one of the fastest-growing demographics within the video game community. As video games become more popular, they are also becoming part of pop culture. Video games have also spawned online communities, competitive tournaments, art, and entertainment. Video games are often played with others and are a social experience. Arcade machines traditionally allowed up to two players, and consoles expanded the experience by allowing four players. With the Internet, players can now play with extremely high numbers of people.

Video game players have been shown to have better hand-eye coordination, visuomotor skills, resistance to distractions, and ability to decipher objects or situations than their nonplayer counterparts. Video games are usually more demanding than traditional board games, and a player must first learn how to operate the proper game controls and interfaces. The way learning is approached in games has been adopted by different education systems and promotes a hands-on approach to learning. Other possible benefits of playing video games are that it helps promote self-esteem, relieve stress, and promote social interaction between players.

Due to adult content such as sex, violence, drug use, profanity, and criminal activity, video games have received backlash from parents, religious groups, and advocacy groups. Video games are given ratings based on content within games similar to how a movie is a rated. In the United States, the Entertainment Software Rating Board (ESRB) rates games based on their content. In Europe, the Pan European Game Information (PEGI) system was created to rate games similar to the ESRB.

Electronic sports, also known as e-sports, have gained immense popularity. Fighting, first-person shooters, multiplayer battle online arenas, and real-time strategy games have become the most common types of video games to appear in e-sports. Players compete with one another in tournaments, and cash prizes have been as high as \$24 million. Players that compete are often referred to as professionals. The U.S. government also recognizes e-sports players as professional athletes. The main medium for viewing e-sports has been Internet live streaming; however, media networks such as ESPN have also displayed e-sports.

Video Streaming Services

Video streaming services allow the user to watch an active stream of video over the Internet. In the past, a user had to download a video to watch it. Streaming is a delivery medium that allows viewers watch video that has not downloaded (a process that forces users to electronically obtain the entire file before opening it for any purpose). YouTube and Netflix are popular streaming content providers.

YouTube was invented by Steve Chen, Chad Hurley, and Jawed Karim. The three were coworkers at PayPal. Karim says their inspiration for the idea came after the Super Bowl halftime incident in which Janet Jackson revealed her breast. Karim was searching for a video of the incident but could not find one online. This gave them the idea of creating a video sharing site. YouTube was activated on February 14, 2005, and the first video was uploaded in April 2005. Chen, Hurley, and Karim sold YouTube to Google for \$1.6 billion on October 9, 2006.

After YouTube was created, Netflix expanded from a DVD delivery service to a streaming media service by providing instant online access to a variety of movies. Along with Netflix in 2007, Apple TV appeared, and in 2008, Hulu launched. Because so many streaming media sites are available, it has become popular to cancel cable subscriptions and instead hook up smart TVs to Netflix, YouTube, Amazon, and Hulu, and so on. Having instant, online access to a variety of TV shows and movies has taken priority over a cabinet full of DVDs.

Video streaming has grown into live video streaming. In 2011, Twitch.tv was launched as a platform for video gamers to video themselves live and interact with other gamers. By 2015, Twitch had about 100 million visitors per month and over 1.5 million broadcasters. In 2017, Twitch launched an “In Real Life” channel where people video themselves live doing just

about anything. In August 2015, Facebook released its live video feature to select celebrity users. Facebook Live launched publicly in September 2016. On September 26, 2016, Facebook teamed up with ABC to stream the Donald Trump debate versus Hillary Clinton via Facebook Live. Over 28 million people tuned in live, and so Facebook Live was put on the national radar.

Virtual Reality (VR)

Virtual Reality (VR) is a simulation of a three-dimensional environment created by electronic equipment. It attempts to create the feeling of virtual presence—the impression that the user is actually present in a virtual environment. A virtual environment is a three-dimensional, 360-degree space generated by a computer. Audio is almost always included in these experiences and used both for sound effects and as music. Creating other kinds of sensations such as touch is less common, but it is being developed. Usually, one looks around the virtual area, interacts with objects, and moves through the space by moving one’s body much as one would in the physical world.

There are several devices commonly used to create these environments. Goggle-like headsets cover a user’s eyes, taking advantage of parallax to create the

illusion of three-dimensionality. These headsets may include speakers, or separate headphones may be used. Headphones often have stereo sound to increase immersion in the artificial environment. Developers are working on tactile feedback to recreate the feeling of touching objects. In certain VR parks, it is possible to have a physical room mirror the virtual environment, so a rock in game will physically exist in reality, but this is not practical for use in the home. So far, most tactile feedback is limited to vibrating controllers. Research is looking into improving feedback for all senses.

The degree and method of interactivity may vary from system to system. The most common feature is the ability to “look around” in these environments. The image projected will react to users moving their heads, mirroring the visual changes that would be expected in the real world. A user’s movement through virtual space may be manipulated by remote controllers, a camera may pick up the user as they walk through a room in real life and mirror that motion in the space, or a multidirectional treadmill may be used to track movement. Controllers can also be used to interact with virtual objects. Some newer devices can pick up the motion of a controller in space, and so a user can move the controller in real life to interact with an object in the virtual space. Ideally, developers want devices that allow users to interact with virtual environments as naturally as possible.

As the technology for VR is still being developed, there remain many issues. The system can be a hassle to get set up, discouraging casual consumers. Headsets are often heavy and cumbersome, as they must be connected with wires to a computer. Price may also be an obstacle to widespread commercial use, though the cost has gone down in recent years. It should be noted that in addition to the cost of the system itself, a computer capable of running VR will likely run over a thousand dollars. In fact, most computers are not able to run VR systems at all, due to the intense graphical processing required. This intense processing also limits picture quality and the system’s reaction time.

One of the biggest issues is that many people become nauseated while using VR. In both video games and VR, movement may be shown on screen, but if the user is not moving this may cause nausea.

However, nausea may be even worse in VR. It is worsened by delayed reaction time from VR devices, which creates a disconnect between user actions and the visual output. Refresh rate—how often a display changes frames—is still low compared to most video games. This decreases visual quality and increases the chance that someone will become nauseated.

There are numerous other potential applications for VR, from entertainment to the practical. For example, VR can replicate the feeling of watching a movie on a theater-size screen or allow one to watch a three-dimensional movie, one that a user can look around and see from different angles. Another application is in social interactions, such as creating a three-dimensional videoconference. A more practical use is in training, especially for things that may be dangerous or impossible to train for in real life. Simulations are often used to train pilots and soldiers, and more kinds of VR training may be seen in the future. VR exposure therapy for public speaking may be just as effective as group therapy, and as the technology becomes more available, it may be a cheaper and more convenient alternative. Other applications may be considered in the future as well.

Currently, the most common use for VR is video games, and most systems commercially available are focused on games. The idea of a three-dimensional, interactive environment fits right in with video games, which try their best to represent these kinds of environments on a flat screen. Video games often desire greater immersion for players, and VR can offer a step in that direction by allowing three-dimensional environments to actually appear three-dimensional. Eventually, one may be able to interact with virtual environments as if one is really there. This appeals to many adventure-seeking gamers.

As recently as five years ago, there were no commercially available VR devices, but this is quickly changing. In the past couple of years, VR has become affordable enough for individual buyer, though prices are still in the hundreds of dollars. Today, there are several commercially available VR products.

The Oculus Rift became available in March 2016 and is currently focused on gaming, but it offers other applications as well. It uses the headset itself as a controller—for example, one looks at a menu option

for a few seconds to select it, or controls a paddle in a 3-D version of *Pong* by moving one's head. Control is sometimes supplemented with a video game controller, which is necessary for games that require more complex controls. The Vive's release marked a renewed interest in the field of VR.

The HTC Vive was released by the gaming company Steam in April 2016 and is almost exclusively for games. It creates virtual rooms that match the dimension of the real room a user is in. Then it tracks their movement within the real room to move them through the virtual one. The Vive also comes with two controllers that track movement and are used to interact with objects and perform other commands. Many consider the Vive the best commercially available VR system at the moment.

Intel, meanwhile, is working on technology specifically aimed at alleviating some of the problems with VR through Project Alloy. Rather than working on a specific device, Intel intends to work with different hardware manufacturers to create several different headsets. Alloy has a feature called “inside-out tracking,” meaning that the headset tracks itself rather than being tracked by some outside device. This helps reduce the complexity of setup for the user. The headset will be wireless, eliminating the problem of tripping on wires. It has a camera that makes a 3-D map of the room the user is in automatically, unlike the Vive, which must be set up by the user. It can even take into account objects inside a room, turning a table into a fountain, for example.

On the simpler end of things, Google Cardboard allows one to turn a smartphone into a rough VR headset by placing it in a cardboard head mount. This is not only extremely cheap but extremely easy to implement, making it by far the most accessible VR system. However, it lacks power compared to other devices. The controls are limited to moving the phone through space, and it seems it may mainly be for watching three-dimensional videos rather than playing games. Even the games that are available for it must be very simple. Its accessibility is its main asset, allowing just about anyone with a smartphone to experience VR.

With the rush of development in the past few years, it seems likely that VR will gain popularity going forward. Not only are new systems being

released, but developers will have more time to release applications for those systems. Devices are becoming smaller, lighter, and easier to use. Newer devices also have better tracking, leading to less motion sickness. As developers work out the problems and new products are released, prices will fall, and more people will be drawn to VR. Some predict that in the not-too-distant future, VR will be commonplace.

Wang, An (1920–1990)

An Wang, a Chinese-born American inventor, engineer, and business executive, built important inventions relating to computer memory and electronic calculators. He founded Wang Laboratories Inc. and served as its executive officer. It was a leading American manufacturer of computers and word-processing systems.

Wang was born on February 7, 1920, in Shanghai, China. He learned English at home from his father before beginning formal schooling at the age of six, when he started the third grade. In high school, he developed an interest in radio and built his own radio

unit. He then entered Chiao-Tung University in Shanghai, where he studied communications engineering. With the start of World War II and the Japanese invasion of China, Wang left Shanghai for inland China, where he designed radio receivers and transmitters for use by the Chinese military.

Wang came to the United States in 1945, where he entered Harvard University in Cambridge, Massachusetts. Funded by a stipend from the Chinese government, Wang completed his master's degree in communications engineering in one year. After working briefly for an American company, Wang took a position with the Canadian office of the Chinese government. In 1947, he returned to Harvard and quickly completed his doctorate degree in engineering and applied physics. In 1949, Wang married, and he and his wife had three children. Wang became an American citizen in 1955.

In 1948, Howard Aiken hired Wang to work at the Harvard Computation Laboratory. Aiken tasked Wang to develop a system for retrieving and storing data in a computer by using magnetic devices. Wang focused his research on the magnetic properties of small, doughnut-shaped rings of ferromagnetic material, which were capable of becoming highly magnetized. Wang soon developed a process whereby data stored on one of these rings could be read by running a current around it.

Researchers at the Massachusetts Institute of Technology (MIT) were also interested in the idea of magnetic core storage of data and had developed it for use in various computers. In a 1950 article coauthored with another Shanghai-born scientist at Harvard, W. D. Woo, Wang announced the results of his work. He patented his invention and, despite a long court fight, earned substantial royalties from International Business Machines (IBM) and other computer manufacturers who used his magnetic core memories as a basic part of computers into the 1970s.

Unhappy that others were profiting from the development and sales of his inventions, Wang left the Computation Laboratory in 1951 and used his life savings to start his own company. Wang Laboratories built and sold a number of products, including custom-built magnetic shift registers for storing and combining electronic signals, and devices for magnetic

tape and numerical control. In the mid-1960s, Wang invented a digital logarithmic converter—a desktop calculator—that allowed people to electronically perform routine arithmetic calculations at high speed and relatively low cost. Desktop calculators soon replaced the traditional machines with mechanical parts and one processing unit. Wang soon saw that the introduction of other technology would permit competitors to sell electronic handheld calculators at much lower prices.

Confronted with the need to find new products, Wang focused his company's efforts on the manufacture of word processors and small business computers. The devices were designed for easy access by those unfamiliar with computers, for broad database management, and for routine business calculations.

By the mid-1980s, Wang Laboratories, which had begun in a room above an electrical fixtures store in Boston, employed over 15,000 people working in several buildings in the manufacturing town of Lowell, Massachusetts, and in other factories and offices throughout the world.

In 1982, Wang Laboratories generated more than \$1 billion per year; by 1989, sales were as high as \$3 billion a year. Wang died of cancer in March 1990 at the age of 70; the company fell on hard times in the early 1990s, when it filed for Chapter 11 Bankruptcy.

Wang's engineering insight and business success made him a fellow of the Institute of Electrical and Electronic Engineers and a fellow of the American Academy of Arts and Sciences. He received an honorary doctoral degree from the Lowell Technological Institute.

Williams, Roberta (1953–) and Ken (1954–)

Roberta and Ken Williams are known for being the founders of the video game developing and publishing company Sierra Entertainment Inc. At this company, the Williamses created the popular franchise *King's Quest*, which spanned up to 9 games, with the 10th game being a reboot that was released in 2015.

Roberta Williams was born on February 16, 1953, and raised in La Verne, California. When she was younger, she was said to have had “the greatest imagination of the 20th century.” Roberta Williams did not have any interest in video games or computers until she married Ken. In 1979, there were few adventure-style video games. Roberta wrote and created *Mystery House* with the help of her husband.

After the successful launch of *Mystery House*, Roberta started to create a new adventure video game

called *King's Quest*. It allowed the player the full ability to control the character, redefining the adventure video game genre. Most adventure computer games during this time were text based. The game sparked a popular series that included seven sequels and three companion novels. Due to this, Roberta was named the “queen of the graphic adventure.”

Ken was born on October 30, 1954, in Evansville, Indiana. After graduating high school a year early at the age of 16, he majored in physics in college. He became a computer programmer at the Control Data Institute trade school in Los Angeles, California. When Roberta had the idea for *Mystery House*, Ken aided her in the computer programming and coding aspects of the game. Ken used a Versawriter to create *Mystery House*. This machine allowed them to create a drawing placed on the screen of the machine, which was then traced by an arm. However, the files created by Versawriter were too large for to fit on the floppy

Roberta and Ken Williams, cofounders of Sierra On-Line, an American video game development company. (John Storey/The LIFE Images Collection/Getty Images)

discs of the time, so Ken began work on a better version of Versawriter before completing *Mystery House*. Once *Mystery House* was released and an ad was published for it in *Micro Magazine*, the game gained positive feedback. The couple (now the parents of two children) then decided to create a video game company.

Roberta and Ken Williams soon became cofounders of the video game development company Sierra Entertainment. It became one of the top consumer software companies, with a huge distribution of products across the world. Sierra Entertainment was sold in 1996, and Roberta and Ken Williams retired from the company in 1998.

Wireless Communication

Wireless communication, also referred to as “telecommunications,” refers to any mode of information transmission over a short or long distances without the use of wires, cables, or any other form of solid electrical conductor. The United Nations International Telecommunication Union similarly defines telecommunications as the transmission, emission, or reception of any signs, signals, or messages by means of electromagnetic systems. This can assume various forms, though

“wireless communication” is often used synonymously with “radio transmission,” with the medium being the lower or upper atmospheres, or space. First originating in the 19th century, wireless communication is now a keystone of modern society affecting all aspects of human life, ranging from instant intercontinental communication between governments and movements to social communication in interpersonal relationships. It has been cited as having made the world smaller, as people can be directly informed of affairs across the world that they would not be privy to in the absence of communications technology.

The inception of wireless communication began with Scottish scientist James Clerk Maxwell (1831–1879), who was the first to mathematically prove the existence of electromagnetic waves in 1865. In 1887, Heinrich Rodolf Hertz (1857–1894) first sent and received electromagnetic waves through a spark transmitter and resonator receiver, thus practically demonstrating Maxwell’s proof and the existence of radio waves.

However, the age of radio is often cited as beginning with Italian electrical engineer Guglielmo Marconi (1874–1937). Privately educated but showing immense interest in the research of Maxwell and Hertz, Marconi experimented with their theories on his father’s country estate at Pontecchio, managing to send and receive the first wireless Morse code signals over a distance of 1.5 miles in 1895. The next year, he transported his apparatus to England and filed the first patent for a system of wireless telegraphy. After a number of successful demonstrations in London, Salisbury plain, and across the Bristol Channel, Marconi formed the Wireless Telegraph and Signal Company Limited (later Marconi Telegraph Company Limited) in 1887. He managed his longest-range transmission yet in that year over a distance of 12 miles, and in 1899, he established wireless communication across the English Channel between England and France. In 1901, he attempted to prove that radio waves would be unaffected by the earth’s geodesic curvature. Retrieving his patent number 7777 for “tuned or syntonetic telegraphy,” Marconi sent the first wireless signal across the Atlantic Ocean—2,100 miles between Poldhu, Cornwall, and St. John’s, Newfoundland, Canada.

Between 1902 and 1912, Marconi would patent other inventions mostly relating to his work on radio waves. Among them were a magnetic detector that would become the standard wireless receiver for years, the horizontal directional aerial antenna, and a “timed spark” system for generating continuous electromagnetic waves. He won the 1909 Nobel Prize for his work in wireless transmission. In 1932, after his 1920 discovery of short-wave radio (1.6 to 30 MHz wavelength), the world’s first radiotelephone link was established in Vatican City with the pope’s summer residence at Castel Gandolfo. After his death in 1879, Marconi was remembered as the father of modern communication technology.

Alexander Graham Bell’s patent for the telephone was filed in 1876, but it was not until J. A. Fleming’s patent of the diode in 1904 and Lee de Forest’s triode amplifier that wireless radiotelephony became possible. The year 1907 saw the rise of the commercial transatlantic wireless service, whose use of massive ground stations marked the end of cable-based telegraphy. In 1915, the first transmission of human voice reached San Francisco from New York, followed five years later by the first commercial broadcast. Before the onset of World War II, which would see a massive climb in wartime telecommunications research, the British Broadcasting Corporation began experiments in the technology known today as “television” in 1930. In 1958, the first telecommunications satellite, Project SCORE (Signal Communications by Orbiting Relay Equipment), was launched by an American Atlas rocket. Wireless communications reached a new revolution in 1969 with experiments in creating multinode computer networks with no centralized mainframe. The first was a four-node network connecting computers at four American universities that became known as ARPANET. This became the precursor to the modern-day Internet, which at its inception used old telephone and television wireless networks.

Wireless communication is known for its many advantages, both traditional and modern, that guided its selection as the dominant communications medium. It can convey information quickly and near instantaneously, reduce necessary hardware, reach remote areas, and address urgent situations using mobile devices. It is also more cost-effective. It is also vulnerable in

ways that were unknown in old cabled systems: the nature of wireless signals broadcasting in a medium makes them vulnerable to remote intrusion from eavesdropping and hacking, though this can be prevented by wireless intrusion prevention technology.

There are various forms of wireless communication suited for varying ranges and functions. Infrared signals use infrared (IR) radiation: electromagnetic waves at wavelengths above visible light and below microwaves. They are short-to-medium-range signals used primarily for communications and security control, as they require unobstructed line of sight between the photo light-emitting diode (LED) transmitter and photodiode receiver. Broadcast radio is the most common form of wireless communication and dispatches audio signals through the atmosphere as radio waves (electromagnetic waves between 300 GHz and 3 kHz in frequency). These can operate on frequency modulation (FM), encoding the audio information on varying frequencies, or amplitude modulation (AM), encoding the wave’s amplitude on a constant frequency. Microwave radio involves super-high-frequency (1 to 30 GHz) radio waves, almost always between ground stations and satellite communications systems. They require line of sight and operate two frequencies on single antennas but are vulnerable to adverse weather conditions. Satellite communications are simply space-based radio, uplinked to and from ground-based stations to onboard transponders. A single transponder can process 155 million bits per second, and a single satellite carries 24 to 72. Other forms of wireless communication are rare and almost exclusively short-range, line of sight signals: ultrasonic technology operates by sound higher than human hearing (22.1 kHz), electromagnetic induction transmits voltage through changing magnetic fields and is used in radio-frequency identification (RFID) technology, and free-space optical uses visible light in the atmosphere or space.

Wireless communications reached their modern culmination with the Internet, which still uses radio frequencies (2.4 to 5 GHz). With the advent of wireless routers, it is now possible for anyone to access this massive computer network for almost any location where radio waves can travel freely. It has provided the opportunity to connect other forms of hardware to

remote control (i.e., car ignitions, household heaters, lights, etc.) in an “Internet of things” using the same wireless frequencies used to communicate. This has also opened the door to new threats, as Internet accessibility enables intrusion by malicious parties, heralding a new revolution of “cyberwarfare.”

YouTube

YouTube is an international video-sharing domain established in San Bruno, California, in February of 2005. The site was created by Chad Hurley, Jawed Karim, and Steve Chen, three former PayPal workers.

The site is a format that allows anyone in the world to upload videos as well as to share, rate, and comment on others' videos. People can upload documentaries, news, self-made media, previews, and/or video clips of movies and shows, and so on. YouTube created a forum for artists in the music industry to upload their content for profit through channels such as Vevo. Users are allowed to view videos when unregistered, but they may contribute their own videos when they register via e-mail or create an account.

However, not all types of videos are allowed to be uploaded. The video must be deemed appropriate for all ages. If a certain video is considered inappropriate for those under the age of 18, it is blocked for the normal public to view and can only be accessed if a user logs in to confirm his or her age. Videos that viewers consider inappropriate can be “flagged,” or rated as a threat. Google purchased the domain in November 2006. YouTube also offers special videos that require purchase among its sea of free videos. This service is called YouTube Red.

Index

Boldface numbers refer to volume numbers.

- Abbe, Cleveland (1838–1916), **2**:7–9
 Monthly Weather Review founded by, **2**:8
 National Geographic Society cofounder, **2**:8
- Abbott, John G., **1**:210–211
- Abbott Laboratories, **1**:179
- AC generator and transformer, **2**:9–10
 at Chicago World’s Columbian Exposition, **2**:58, 63, 107
 Great Barrington Electrification, **2**:9, 62
 primary document: AIEE biography for William Stanley (1934), **2**:10
 and “war of the currents,” **2**:9, 58, 62–63
- AC induction motor, **2**:10–11, 148
 primary document: Tesla’s patent (1896), **2**:11–14
- Acetylsalicylic acid. *See* Aspirin
- Acquired immune deficiency syndrome (AIDS). *See* AIDS research
- Adams, Ansel, **2**:293; **3**:80
- Adams, John, **1**:8, 10, 144, 260
- Adams, Thomas, **2**:157, 210
- Addams, Jane, **2**:172
- Adding machine with keys, **2**:14, 114
- Adding machines, **2**:14, 113–114
 Arithmometer, **2**:113–114
 automatic calculation, **1**:113–114
 clearing lever (“machine gun of the office”), **2**:114
 Comptometer, **2**:113–114
 Dalton Adding Machine (10 numerical buttons), **2**:114
 and industrialization of leisure, **2**:5
 and paper copies of tabulations, **1**:114
 See also Calculators
- Additive manufacturing. *See* 3-D printing
- Adhesive bandages, **2**:185. *See also* Band-Aid
- Adhesive tape, **1**:174–175
 Band-Aid, **1**:175; **2**:175, 185
 duct tape, **1**:175; **2**:256
 masking tape, **1**:175; **2**:113, 218, 241
 Scotch Tape (cellophane tape), **2**:113, 218, 241, 253
 as staple in American homes, **2**:253
 uses for, **1**:175
- Advanced Research Projects Agency Network. *See* ARPANET
- Aerosol spray can, **2**:176
- Aerosols
 and carbon capture and storage (CCS), **3**:40
 and chlorofluorocarbons (CFCs), **2**:176; **3**:38
 and Clean Air Act (1977), **2**:176
 definition of, **2**:176
 and Freon, **2**:205
- Agassiz, Elizabeth Cabot Cary, **1**:176, 259
 American Philosophical Society member, **1**:9
 Louis Agassiz: His Life and Correspondence, **1**:176–177
- Agassiz, Louis (1807–1873), **1**:46, 175–176
 primary document: excerpt from journal (1846), **1**:176–177
- Age of Reason. *See* Enlightenment
- Agent Orange, **3**:9–10
 discontinuation of use of, **3**:7
 naming of, **3**:9
 Operation Pacer IVY (removal of barrels from Vietnam), **3**:10
 producers of, **2**:50; **3**:9
 protests against, **3**:7
 toxicity and health effects of, **3**:9–10
- AI. *See* Artificial intelligence (AI)
- AIDS research, **3**:171–173
 AZT (zidovudine, drug treatment), **3**:172, 197
 discovery of HIV, **3**:172
 Doha declaration, **3**:172
 ELISA blood test, **3**:172
 first verified HIV case, **3**:171
 highly active antiretroviral therapy (HAART), **3**:172
 history of HIV/AIDS, **3**:171
 HIV mutations, **3**:173
 and Kaposi’s sarcoma, **3**:171, 173
 and medical technology, **3**:249
 and National Institutes of Health, **2**:105; **3**:173, 175
 and pneumocystis carinii pneumonia (PCP), **3**:171, 173
 prevention of HIV transmission, **3**:172
 primary document: introduction to AIDS archive by C. Everett Koop, **3**:173–177
 rapid HIV tests, **3**:172, 249
 and research by Salk, Jonas, **3**:126
 saquinavir (drug treatment), **3**:172
